Executive Summary

This report provides information about the estimated number of unintentional electrocutions associated with the use of consumer products in 2007, and companion statistics since 2002. This report was prepared by U.S. Consumer Product Safety Commission (CPSC) staff.

It is important to note that the electrocution incidents covered in this report were associated with a consumer product, but were not necessarily caused by the product.¹

Some of the key findings in this report are:

- There was an estimated average of 60 electrocution fatalities² associated with consumer products per year over the three-year period from 2005 through 2007, with an estimated 50 consumer product-related electrocutions in 2007.
- The age-adjusted death rate for electrocutions due to consumer product use was 0.17 per million population for 2007, with the three-year average from 2005 through 2007 being 0.21. Tests indicate that there is no statistical evidence of a trend in the electrocution death rate from 2002 to 2007.
- Victim age appears to be a factor in electrocution incidents. During the period covered by this report (2002–2007), there were more than twice as many electrocutions to victims 40 through 59 years old than there were to victims 19 years of age and younger, even though the U.S. population in these age groups is roughly equal.
- There were nearly six times as many estimated consumer product-related electrocutions to males than to females over the years 2002 through 2007.
- The three most common product categories associated with electrocutions over the three-year period 2005–2007 were “Small Appliance,” “Power Tool,” and “Lighting equipment.”

¹ Not all of these fatalities are addressable by an action the CPSC could take; however, it was not the purpose of this report to evaluate the addressability of the incidents, but rather, to update the estimates of the number of consumer product-associated electrocutions.

² Estimated electrocutions are rounded to the nearest 10.

Introduction

This report was prepared by U.S. Consumer Product Safety Commission (CPSC) staff and contains estimates of the number of nonwork-related electrocutions involving consumer products and the corresponding age-adjusted death rates from 2002 through 2007. National estimates of consumer product-related electrocutions are derived from in-scope death certificate records contained in CPSC databases.

This report contains annual estimates for consumer product-related electrocutions for 2002 through 2007. The three-year average of the latter three years is also presented. In addition, this report presents a breakdown of consumer product-related electrocutions by victim age group and gender, as well as by age-adjusted mortality rates for direct comparison of year-to-year data. Finally, there is a breakdown by product category (e.g., “Small Appliance” or “Power Tool”).

National Estimates of the Number of Product-Related Electrocutions

The basis for national estimates of the number of consumer product-related electrocutions per year is the number of in-scope fatalities reported to CPSC staff through death certificates. An in-scope case is any accidental electrocution in which a consumer product was involved (e.g., power drill or microwave oven) and that was not work-related. CPSC records contain the majority of death certificates identified as electrocutions. The National Center for Health Statistics (NCHS) has records of every electrocution that occurred in the United States. NCHS records, however, lack product information. National estimates are generated by scaling or projecting CPSC records using NCHS record totals. Additional details on the scope definition used for this report are provided in Appendix A.

Table 1 provides a summary of electrocution death certificate records in NCHS and CPSC databases, as well as national estimates of consumer product-related deaths generated by CPSC staff. National estimates are determined by projecting the ratios of the in-scope fatalities to total electrocution records in the CPSC database onto the NCHS electrocution records totals. The basic assumption of this approach is the expectation that the records contained in the NCHS database that are missing from the CPSC database would have the same characteristics of the data that is captured in the CPSC records. Specifics of the scaling procedure can be found in Appendix B. **Table 1: Electrocutions in the United States, Including Estimates of Consumer Product-related Electrocutions, 2002–2007**

Year	NCHS Electrocutation Records ¹	CPSC Electrocutation Records ²	CPSC In-Scope Records ³	CPSC Staff National Estimates ⁴	Percentage of CPSC Electrocutation Records that are in scope
2002	432	397	51	60	13%
2003	377	344	56	60	16%
2004	387	358	56	60	16%
2005	394	350	83	90	24%
2006	390	348	41	50	12%
2007	370	233	32	50	14%
Total 2002-2007	2350	2030	319	370	16%
Average 2005-2007	385	310	52	60	--

¹ NCHS records are considered a census of all electrocution records in the United States, but lack product information.

² CPSC records, including death certificate records, used in the determinations of whether a fatal incident is in-scope or not.

³ CPSC In-Scope Records represents proportionately scaled counts after allocation of electrocution incidents with unknown location and/or scope (see Appendix B for details).

⁴ Estimated in-scope electrocutions after scaling of estimated CPSC in-scope records to account for differences in NCHS totals (census) and CPSC records. Estimates have been rounded to the nearest 10.

The national estimates of consumer product-related electrocutions for 2005 were somewhat higher than estimates for the previous three years and the subsequent two years. There is insufficient information available to CPSC staff to determine what caused the apparently higher number of electrocutions in 2005. CPSC analysts hypothesized that the spike may be weather related, due to the higher than normal levels of hurricane and ice storm activity during 2005. A review of the dates and locations of the electrocutions failed to support this hypothesis. Very few electrocution incidents occurred in the areas severely hit by hurricanes and ice storms, and fewer still occurred in the days following the storm events.

National Estimates of Electrocutation Rates

Table 2 provides the national consumer product-related electrocution estimates categorized by age group of the victims. Table 3 gives the age-specific mortality rates and age-adjusted death rates per one million population from electrocutions based on the standardized Year 2000 U.S. population. The Year 2000 population standard has been adopted for age-adjusting death rates in the United States by the NCHS, the Centers for Disease Control and Prevention (CDC), the U.S. Department of Health and Human Services (HHS), as well as many state vital statistics programs. Using an age-adjusted death rate standardized to a specific year allows for direct comparison of death rates between years, compensating for the changes in population age distribution.

**Table 2: National Estimates of Consumer Product-Associated Electrocutions
Categorized by Age of Victim, 2002–2007**

Age of Victim	Total 2002-2007	2002	2003	2004	2005	2006	2007	Average 2005-2007

60 and over	69	12	20	11	14	10	3	9
All	368	56	61	61	93	46	51	63

Note: Details may not sum to row and column totals due to rounding.

**Table 3: Estimated Age-Specific and Age-Adjusted Electrocutation Rates (per 1,000,000)
Associated with Consumer Products, 2002–2007**

Age of Victim	2002	2003	2004	2005	2006	2007	Average Rate 2005-2007 [#]
< 1 - 19	0.167	0.185	0.068	0.199	0.061	0.092	0.117
20 - 39	0.184	0.138	0.187	0.348	0.199	0.245	0.264
40 - 59	0.193	0.189	0.359	0.425	0.179	0.241	0.282
60 and over	0.255	0.417	0.227	0.272	0.198	0.048	0.173
Electrocution Rate, All Ages	0.193	0.211	0.208	0.315	0.155	0.168	0.213
Standardized Age- Adjusted Rate*	0.193	0.210	0.204	0.313	0.154	0.168	0.212

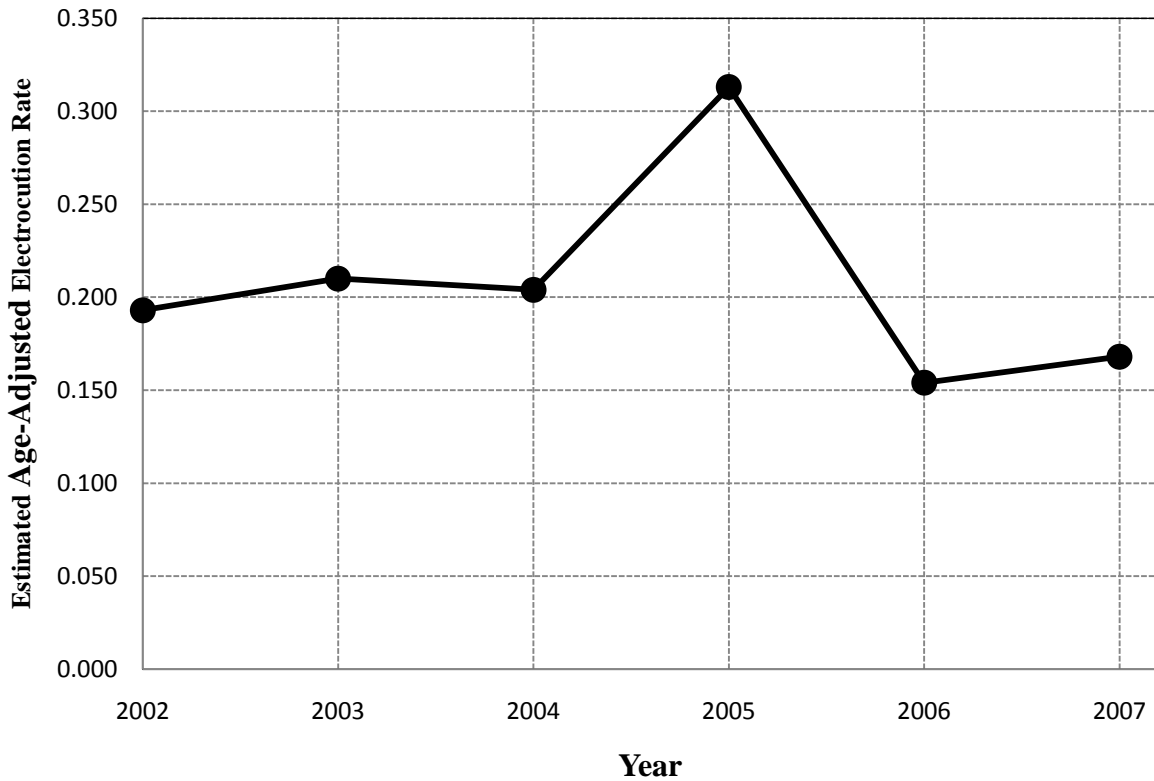

[#] Average Rate is the average of the annual within age group fatality rates for the years 2005 through 2007.

* Standardized to Year 2000 Population, U.S. Census Bureau, Statistical Abstract of the United States: 2010

There were fewer electrocutions to young consumers (19 years of age and younger) than might be expected, given the number of the U.S. population that is in that age range. For example, the six-year average U.S. population of individuals younger than 20 years of age (81.553 million) is slightly higher than the average population size of individuals 40 to 59 years old (81.492 million); yet the estimated total number of electrocutions from 2002 through 2007 in the older age group was more than double that of the younger group (130 versus 63, a ratio of 2.06 to 1).

Over the last three years, the difference is even greater. From 2005 through 2007, there were an estimated 70 consumer product-related electrocutions to consumers aged 40 to 59, while there were 29 electrocutions to consumers younger than 20 (a ratio of 2.41 to 1). A Pearson’s Chi-Square Test for Independence was performed on the 2002–2007 six-year average electrocution estimates to determine if there was statistically significant evidence that age was a factor in electrocution incidents.³ The statistical test rejected independence, which would indicate that age is a factor in electrocution incidents. Figure 1 presents the estimated age-adjusted annual electrocution rates for the years 2002 through 2007.

Figure 1: Estimated Age-Adjusted Annual Electrocution Rates (per 1,000,000) Associated with Consumer Products, 2002–2007

There does not appear to be a trend in the electrocution rates. To test this hypothesis, a regression analysis was performed to determine if there was sufficient evidence to conclude that there was a trend in the estimated age-adjusted electrocution rate over the period from 2002 through 2007. The results of the analysis indicate that there is insufficient evidence of a trend in the electrocution rates over this time period.⁴ Details of the analysis are provided in Appendix C, with the Analysis of Variance table provided as Table C3.

³ See Appendix C for details.

⁴ No trend was declared unless the attained significance (p-value) of the statistic was < 0.05.

Table 4 presents the national estimates of electrocutions characterized by gender. As can be seen in the table, male victims comprise the large majority of electrocutions, accounting for 89 percent (170 of 190) of all consumer product-related electrocutions over the three-year period 2005–2007.

Table 4: National Estimates of Consumer Product-Associated Electrocutions Categorized by Gender of Victim, 2002–2007

Gender of Victim	Total 2002-2007	2002	2003	2004	2005	2006	2007	Average 2005-2007
Female	53	15	6	12	7	5	8	6
Male	315	41	55	49	86	41	43	57
All	368	56	61	61	93	46	51	63

Note: Details may not sum to row and column totals due to rounding.

There are far fewer electrocutions to female consumers than might be expected given the proportion of the U.S. population that is female. The six-year average U.S. population of females is slightly higher than the average population of males (149.519 million and 144.822 million, respectively); yet the estimated number of electrocutions to males is nearly six times greater than to females. A Pearson’s Chi-Square Test for Independence rejected independence, which would indicate that gender is a factor in electrocution incidents.⁵

Number of Reported Electrocutions by Product Type

Product and product category summaries in Table 5 are presented as actual observed frequencies in the CPSC death certificate databases and are not national estimates. Because of the broad distribution of incidents over many products and product categories, the specific counts are small and would not show any change when applying scaling factors.

The three most common product categories associated with electrocutions over the three-year period 2005–2007 were “Small Appliances” (21 deaths, or 17 percent of reported consumer product-related electrocutions), “Power Tools” (13 deaths, 10 percent), and “Lighting Equipment” (11 deaths, 9 percent). The most common scenario for electrocutions involving small appliances was the consumer being electrocuted while attempting to repair the appliance. The most common scenario for electrocutions involving power tools was the equipment coming in contact with electrical wires while the consumer was using the power tool. Over the six years covered in this report, the four most common product categories associated with electrocutions were “Large Appliances” (29 deaths, or 11 percent of reported consumer product-related electrocutions), “Small Appliances” (27 deaths, 11 percent), “Power Tools” (24 deaths, 9 percent), and “Lighting Equipment” (24 deaths, 9 percent).

⁵ See Appendix C for details.

APPENDIX A: CPSC Scope Assessments

The CPSC has jurisdiction over thousands of consumer products used in and around the home, in sports and recreation, and in schools. In the cases of electrocution, the following determinate factors were used to assess if the case was in-scope:

- Incidents involving a product under CPSC jurisdiction that comes into contact with an electrical source, such as power lines or household current (e.g., a drill or power saw cutting into an electrical wire), were considered in-scope.
- All work-related incidents were determined to be out-of-scope.
- All incidents involving products outside CPSC jurisdiction were determined to be out-of-scope. Examples of these include, but are not limited to, incidents involving autos, boats, direct contact with power lines, direct contact with household wiring with no other consumer product involvement, and industrial equipment.

When there was insufficient information to make a definitive determination of whether a case was in-scope or out-of-scope, or where apparent contradictions existed, the following assumption was used:

- Incidents involving an individual apparently functioning in his/her regular occupation in which the death certificate indicates that the fatality was not work-related are assumed to be in error. In these cases, the incident was assumed to be work-related. For example, a professional tree trimmer was electrocuted while trimming trees at someone else's residence, yet the incident was classified as not work related on the death certificate. There are many reasons that could explain this discrepancy. First, the death certificate simply may have been miscoded, or the coder may have a different interpretation of the "work-related" question on the death certificate. On many death certificates, the work-related question field states something to the effect of, "Did the death occur at work?" Perhaps the coders interpreted "at work" as referring to an office or factory, and working in a yard of a residence does not fit this interpretation. Finally, it may be possible that the individual actually may not have been "working" but may have been helping a friend or family member. Without evidence of this, however, the incident was assumed to be miscoded.

There are also many cases where one or more key piece(s) of information are missing and a determination cannot be made from the known information. An imputation method (simple proportional adjustment) was applied to adjust the overall and categorical counts, if possible. The key factors to determining scope are:

- Work-related status,
- Location of injury,
- Profession of victim,
- Age of victim (to assist in work-related status determination when this information is not provided),
- Product involved, and
- Activity engaged in when incident occurred.

Even though there may be some key data that is missing, a determination often can be made with limited information. For example, all work-related incidents can be eliminated, regardless of what other information is missing. As another example, if a child is injured, it would be assumed not to be a work-related injury even if work status was missing. In this latter case, the incident would be considered in-scope, unless some other factor would eliminate it, such as the product involved.

Appendix B: Derivation of National Estimates and Age-Standardized Electrocutation Rate Calculations

This appendix describes the data sources and methodology used to compute the national estimates of electrocutions associated with the use of consumer products.

All death certificates filed in the United States are compiled by the National Center for Health Statistics (NCHS) and entered into a multiple cause of mortality data file. The NCHS Mortality File contains demographic and geographic information, as well as the International Statistical Classification of Diseases and Related Health Problems codes for the underlying cause of death. Data are compiled in accordance with the World Health Organization instructions, which request that member nations classify causes of death by the current Manual of the International Statistical Classification of Diseases and Related Health Problems. The International Classification of Diseases, Tenth Revision (ICD-10) was implemented in 1999. Although the NCHS data contain cause of death codes that are helpful in identifying deaths due to electrocution, the data do not contain any narrative information that might indicate the involvement of a consumer product.

To complement the NCHS mortality data, CPSC staff purchases death certificates from the 50 states, the District of Columbia, and New York City. Specifically, CPSC staff purchases death certificates with certain cause of death codes for which there is a high probability that consumer products are involved. In addition to the cause of death codes and demographic and geographic information, the death certificates contain information about the incident location and a brief narrative describing the incident. Any references to consumer products are usually found in these narratives. CPSC staff conducts follow-up in-depth investigations on selected deaths to confirm and expand upon the involvement of consumer products, as resources allow. The in-depth investigation reports, or IDIs, are contained within the CPSC In-depth Investigation (INDP) File. Additionally, information that may help the analyst in the determination of product involvement sometimes can be ascertained from the Injury or Potential Injury Incident (IPII) File, which contains news articles and medical examiner reports associated with an incident.

Searches were conducted on both of the CPSC death certificate databases, Death Certificate (DTHS) File, and Abbreviated Death Certificate (ABDT) File, and the NCHS database to retrieve all electrocution cases available within the relevant timeframe. The search criteria limited the death certificate records to those classified by the ICD-10 codes as electrocutions. These death certificates have one of the following ICD-10 cause of death codes:

- W85 - Accident caused by electric current: Electric transmission lines;
- W86 - Accident caused by electric current: Other specified electric current; or
- W87 - Accident caused by electric current: Unspecified electric current.

The search criteria also constrained the records to those fatalities that occurred between January 1, 2002 and December 31, 2007.

Step 1: Review of CPSC records for scope determination

The first step in computing the annual estimates of electrocutions associated with consumer products is to compile an electrocution dataset of all electrocution death certificates available to CPSC staff. The CPSC's DTHS File and the CPSC's ABDT File were searched for cases associated with ICD-10 codes W85 through W87.

Each death found in the DTHS database coded as an electrocution was reviewed by an analyst and categorized as in-scope, out-of-scope, or unknown scope. In-scope cases are unintentional electrocutions associated with a consumer product under the jurisdiction of the CPSC. Out-of-scope cases are cases that involve products that are not under the jurisdiction of the CPSC, work-related incidents, or intentional electrocutions. The scope of a case was classified as unknown in incidents where a consumer product was possibly associated with the incident, but the product could not be identified explicitly. An example of this might be a consumer who was electrocuted in an incident at his home that was determined to be not work-related, and a product was not identified.

Most deaths found in the ABDT database were categorized as out-of-scope cases. Most of the ABDT File contains death certificates for electrocutions that involve nonconsumer situations, such as a lineman being electrocuted while working on power lines, or electrocutions that involve nonconsumer products, such as motor vehicles and industrial equipment. Occasionally, an analyst's review of an ABDT case results in a case being reassessed to be within— or possibly within—CPSC jurisdiction. The former cases were included as in-scope deaths, and the latter cases were identified as “unknown scope” and were included in the Step 3 phase (Allocation of unknown scope cases to known scope categories within location categories) of the staff's analysis.

Step 2: Allocation of unknown location cases to known location categories

After review of the death certificate records in the two databases (DTHS and ABDT) for scope determination, the data were combined. Location of the incident is an important factor in the determination of whether an incident would be in-scope. For example, based on CPSC records, a significant proportion of residential electrocutions were determined to be in-scope (consumer product- and nonwork-related), while virtually no industrial incidents were within CPSC scope. Table B1 provides a summary of the CPSC electrocution death certificates categorized by location and scope for 2007.

**Table B1: Scope Categorization by Year and Location
of Death in the CPSC Database Records**

2007	Scope			
Location	In	Out	Unknown	Total
Farm	0	7	0	7
Recreational	1	4	1	6
Residential	17	28	26	71
School	0	2	0	2
Public Land	1	28	6	35
Industrial	0	53	0	53
Street	0	32	4	36
Unknown	1	15	7	23
Total	20	169	44	233

Source: U.S. Consumer Product Safety Commission / EPHA.
CPSC Death Certificate File, In-Depth Investigation File, Injury or Potential Injury Incident File,
Abbreviated Death Certificate File.

The totals for death certificates where a location of the death could not be identified were then allocated proportionately among the known location categories based on the observed frequency of occurrence by location. The results of the proportional allocation are given in Table B2. It should be noted that, in order to minimize rounding error, the individual cell counts were kept as fractional numbers until the last stage of the estimation process and are presented to two decimal places in the tables.

**Table B2: Allocation of “Unknown” Location Electrocutions
to Known Location Categories**

2007	Scope			
Location	In	Out	Unknown	Total
Farm	0.00	7.68	0.00	7.68
Recreational	1.05	4.39	1.19	6.63
Residential	17.89	30.73	30.92	79.54
School	0.00	2.19	0.00	2.19
Public Land	1.05	30.73	7.14	38.92
Industrial	0.00	58.16	0.00	58.16
Street	0.00	35.12	4.76	39.87
Unknown				
Total	20.00	169.00	44.00	233.00

Step 3: Allocation of unknown scope cases to known scope categories within location categories
 In this step, the “unknown scope” summary counts are allocated to the known scope categories. This is performed using the observed in-scope and out-of-scope ratios within location categories because of the rationale previously stated about the probability that an in-scope case is dependent upon the location of the incident. Table B3 presents the number of death certificates summarized from the two CPSC databases by scope determination (after allocation of unknowns) and the total number of electrocution records in the NCHS database.

Table B3: Allocation of “Unknown” Scope Electrocutions to Known Scope Categories

2007	Scope			
Location	In	Out	Unknown	Total
Farm	0.00	7.68		7.68
Recreational	1.28	5.35		6.63
Residential	29.27	50.27		79.54
School	0.00	2.19		2.19
Public Land	1.29	37.63		38.92
Industrial	0.00	58.16		58.16
Street	0.00	39.87		39.87
Unknown				
Total	31.85	201.15		233.00

Step 4: Generating national estimates of consumer product-related electrocutions

The proportion of death certificates found in the CPSC databases associated with electrocutions and involving consumer products was applied to the NCHS totals to calculate the total estimated number of electrocutions associated with consumer products. In theory, the NCHS totals comprise all death certificates in the United States, and the same proportion of in-scope cases should exist in the death certificates that are missing from the combined CPSC Death Certificate and Abbreviated Death Certificate files. Applying the proportion of in-scope cases to the NCHS database totals therefore, should provide an estimate of in-scope cases nationwide. This was done separately for each year in the following way:

1. The number of in-scope deaths in the CPSC’s Death Certificate File coded as W85, W86, or W87 that were associated with an accidental, nonwork-related electrocution and a consumer product were identified (n_1).
2. The total number of deaths in the CPSC’s Death Certificate File and the Abbreviated Death Certificate File coded as W85 through W87 was summed separately for each year (n_2).
3. The total number of deaths in the NCHS data coded as W85 through W87 was counted (n_3).

4. The estimate of the number of accidental, nonwork-related electrocutions associated with consumer products in codes W85 through W87 was calculated separately for each year using the formula:

$$N = (n_1 / n_2) * n_3$$

The proportion (n_1 / n_2) represents the number of in-scope cases found in the CPSC’s files divided by the total of in-scope and out-of-scope cases in the CPSC data files.

The ratio (n_3 / n_2) represents the weighting factor used to calculate the annual estimates. The CPSC’s Death Certificate File does not contain death certificates for all deaths listed in the NCHS file; therefore, a weighting factor was calculated to account for those death certificates that are missing. The weighting factor is used to scale-up the CPSC counts to compensate for the records missing in the CPSC databases. Under the assumption that the characteristics of the deaths not contained in the CPSC database follow the same proportions as those in which the CPSC has records, this weighting factor allows for the computation of national estimates of electrocutions by consumer products and by other characteristics collected by the CPSC about each death by scaling up the data observed in the CPSC subset.

The following table contains the values for the variables used in the calculation, as well as the final computed 2007 estimates of electrocutions associated with consumer products.

Table B4: Derivation of Consumer Product-Associated Electrocution National Estimates

	2007
n ₁	31.85
n ₂	233
n ₃	370
<i>Weighting Factor (n₃ / n₂)</i>	1.5880

Step 5: Generating national estimates of consumer product-related electrocutions by age group and calculating age-adjusted death rates

The weighting factors derived above for adjusting the counts for the number of missing records in the CPSC databases were also applied to the age and gender categorizations to develop national estimates by these characterizations. A second weighting factor is also needed to make the age and gender category estimates consistent with the national estimates generated previously. The second weighting factor is a weight to accommodate the scaling up procedure for the “unknowns” outlined in Steps 2 and 3 above. This weight is simply the ratio of the number of in-scope CPSC records after allocation of “unknowns” for a given year to the number of CPSC records where scope and location are known for the same year. The two weights are both multipliers, so they can be combined into one factor by multiplying one by the other. Table

B5 shows the calculation of the weighting factor. Table B6 shows the number of in-scope records in the CPSC’s databases characterized by age group. Table B7 shows the national estimates after the combined weighting factor was applied.

Table B5: Consumer Product-Associated Electrocutation Death Certificates in the NCHS Database and the Combined CPSC Databases After Allocation of Unknowns

	2002	2003	2004	2005	2006	2007
Observed In-Scope Records	37	49	44	69	37	20
In-Scope Records After Allocation of “Unknowns”	51.05	56.00	56.41	82.82	41.35	31.85
“Unknowns” Allocation Weight	1.3798	1.1429	1.2820	1.2003	1.1177	1.5923
Weighting Factor (from Table B4)	1.0882	1.0959	1.0810	1.1257	1.1207	1.5880
Combined weight	1.5015	1.2526	1.3859	1.3512	1.2526	2.5285

Table B6: Consumer Product-Associated Electrocutation Death Certificates in the CPSC Database Categorized by Age Group

Age Group	Total 2002-2007	2002	2003	2004	2005	2006	2007	Average 2005-2007

The crude death rate typically is defined as the number of deaths in a given population during a given time period, divided by the total population, and multiplied by one thousand (or some other population scaler). Crude death rates are a widely used measure of mortality that can be used to compare subpopulations within the greater population of incidents. However, crude death rates are not the best measure when comparing year-to-year death rates. In a National Vital Statistics Report titled, “Age Standardization of Death Rates: Implementation of the Year 2000 Standard,” a rationale for age-adjusting death rate is stated: “... crude death rates are influenced by age composition of the population. As such, comparisons of crude death rates over time or between groups may be misleading if the populations being compared differ in age composition. This is relevant, for example, in trend comparisons of U.S. mortality given the aging of the U.S. population.” For this report, the electrocution incidents were categorized into subpopulations by year of death and age group, and by year of death and gender. The death rates by year/age are presented as standardized death rates using the 2000 U.S. population as the standard. In August 1998, the use of the Year 2000 standard population was established in a policy statement from the Secretary of the U.S. Department of Health and Human Services (DHHS), which directed all DHHS agencies, including the NCHS and the Centers for Disease Control and Prevention (CDC), to use this standard.

The crude death rate is determined by dividing the total number of deaths for a specific characterization by the midyear population for the same characterization. The standardized age-adjusted death rate is calculated by multiplying each age-specific category rate by a standardized weight, which represents the proportion of the population in the specific subpopulation for the given standard year (Year 2000). The products of the age-specific rates and the weights are then summed over age group to produce the age-adjusted rate. Table B8 presents the U.S. population subdivided by age group for the years 2002 through 2007. Table B9 provides the standardized age group weights based on the Year 2000 U.S. Population. Table B10 provides a summary of the calculations to determine age-adjusted death rates for the years 2002 and 2007, standardized to the Year 2000 population.

It should be noted that the age-adjusted death rates for the years 2002 through 2006, presented in Table 3 of the main body of this report, have changed slightly from the previous electrocutions report,⁶ due to changes in U.S. population estimates obtained from the U.S. Census Bureau’s 2010 Statistical Abstract of the United States from the population estimates presented in the U.S. Census Bureau’s 2009 Statistical Abstract, which was used in the previous report.

Appendix C: Statistical Test Results

Chi-Square Statistic–Calculations

Pearson’s Chi-Square Test for Independence was used to determine if the observed distribution on consumer product-related electrocutions was independent of the age of the victim. If electrocutions were independent of age, we would expect the observed proportions of electrocutions in each age group to be similar to the proportions of the U.S. population within the same age group categories. To test this assertion, the observed data, the national estimates total over the six years of this report (2002 through 2007), were compared to the expected number of electrocutions in each age group given the estimated total number of electrocutions observed. The expected number of electrocutions for a specific age group is calculated using the formula:

$$E_i = \left(\frac{\text{population } n_i}{\text{total population}} \right) \times (\text{total estimated electrocutions}),$$

where,

E_i is the expected number of electrocutions in the i^{th} age group, and
population n_i is the average U.S. population (2002-2007) in the i^{th} age group.

$$x^2 = \sum_{n=1}^4 \frac{(O_i - E_i)^2}{E_i}$$

where,

E_i is the expected number of electrocutions in the i^{th} age group, and
 O_i is the observed (estimated) number of electrocutions in the i^{th} age group.

All calculations were performed on the nonrounded estimates.

Table C1 presents the results of the statistical test. The p-value of the test indicates that there is significant evidence to conclude that the observed proportions of electrocutions are not independent and are, in fact, dependent on age. Therefore, we can conclude that age is a factor in electrocution incidents. As can be seen in Table C1, there were far fewer electrocutions in the younger than 20 year old age range than would be expected based on the proportion of the U.S. population in that age range.

Table C1: Chi-Square Test for Independence Table to Determine if Age Is a Significant Factor in Electrocution Incidents

AGE	Average Population (millions)	Electrocutions, Expected	Electrocutions, Observed (Estimated)	Chi-Square Statistic	p-Value (3 degrees of freedom)
< 1 - 19	81.553	101.98	62.90	18.727	
20 - 39	81.826	102.32	106.42	0.205	
40 - 59	81.492	101.90	129.54	9.373	
60 and over	49.470	61.86	69.20	1.089	
ALL	294.341	368.05	368.05	29.395	0.000002

Table C2 presents the results of the Pearson’s Chi-Square statistic testing the assertion that electrocutions are independent of gender. Once again, the p-value of the test indicates that there is significant evidence to conclude that the observed proportion of electrocutions are not independent and, in fact, are dependent on gender. Therefore, we can conclude that gender is a factor in electrocution incidents. As can be seen in Table C2, there were far fewer electrocutions to females than would be expected, considering the proportion of the U.S. population that is female.

Table C2: Chi-Square Test for Independence Table to Determine if Gender Is a Significant Factor in Electrocution Incidents

AGE	Average Population (millions)	Electrocutions, Expected	Electrocutions, Observed (Estimated)	Chi-Square Statistic	p-Value (1 degree of freedom)
Female	149.519	186.96	53.10	119.843	
Male	144.822	181.09	314.95	123.730	
ALL	294.341	368.05	368.05	243.573	0.000000

Regression Analysis of Annual Age-Adjusted Death Rates

A regression analysis was performed to determine if there was sufficient evidence to conclude that there was a trend over time in the age-adjusted fatality rates. For this analysis, the dependent variable was the estimated age-adjusted death rate, and the independent variable was the year. The analysis of variance (ANOVA) table for the regression is given in Table C3.

Table C3: ANOVA Table of Regression Model Testing for Trend in Age-Adjusted Death Rates Due to Electrocutions Associated with Consumer Products

Source	Degrees of Freedom	Sum of Squares	Mean Square	F Value	Prob. > F
Year	1	0.000483	0.000483	0.13	0.7400
Error	4	0.01527	0.00382		
Corrected Total	5	0.01576			

The probability value given in the table is the probability that the regression slope is equal to zero (i.e., that there is no trend). Since the resultant probability value is greater than 0.05, we conclude that there is insufficient evidence to reject the hypothesis that there is no trend. Therefore, we can conclude that there is insufficient evidence of a trend in the age-adjusted electrocution rates.
