Cumulative Effects of Alternative I for Sale 186.	The potential for conflicts arising from the cumulative case is the same as those discussed in Section IV.C Effects Common to All Alternatives. Conflicts with Statewide standards of the ACMP and the policies of the NSB CMP are not inherent in the hypothetical scenarios presented in the cumulative case. Alternative I for Sale 186, represents a small proportion (4%) of the total past, present, and reasonably foreseeable oil and gas development in the Beaufort Sea area. No conflicts are anticipated for activities associated with Alternative I for Sale 186 and its contribution to the cumulative case does not alter the conclusion for the cumulative case. This conclusion is based partly on the small contribution of Alternative 1 for Sale 186, but predominantly on the conclusion that exploration and development and production can proceed consistent with the enforceable policies of the ACMP and the NSB CMP. The MMS regulatory oversight and lease stipulations address many of the concerns applicable to the enforceable standards. In addition, the consistency review of these activities will address the applicable policies at the time that specific plans are submitted.
Air Quality	
Effects Common to Alternatives I, III, IV, V, and VI for Sales 186, 195, and 202.	Effects on onshore air quality from air emissions likely would be only a very small percent of the maximum allowable PSD Class II increments. The concentrations of criteria pollutants in the onshore ambient air would remain well within the air-quality standards. Consequently, there likely would be only a minimal effect on air quality with respect to standards. Principally, because of the distance of emissions from land, the other effects of air-pollutant concentrations at the shore due to exploration and development and production activities or accidental emissions would not be sufficient to harm vegetation. A light, short-term coating of soot over a localized area could result from oil fires. The air-quality analysis is based on the specific emission controls and emission limitations that the operators would apply to meet the appropriate Environmental Protection Agency regulations and permit requirements for any development and production activities. The effects of all these activities would cause only small, local, temporary increases in the concentrations of criteria pollutants. Concentrations would be within the PSD Class II limits and National Ambient Air Quality Standards. Therefore, effects from the proposed sales would be low. Individual air masses move constantly with atmospheric circulation, we expect that the major differences in effects of the different alternatives on air quality would be in which specific geographic areas could be affected by air emissions. Because these emissions should not be significant other than in extremely localized areas, we conclude that none of the alternatives to the proposed sales (186, 195, and 202) would result in significant effects different from or other than those discussed in Section IV.C.15.a. Air quality effects of all activities under all sales and all alternatives would cause only small increases in the concentrations of criteria pollutants. Concentrations would be within the PSD Class II limits and National Ambient Air Quality Standards.
Cumulative Effects of Alternative I for Sale 186.	The cumulative effects of all projects affecting the North Slope of Alaska in the past and occurring now have caused generally little deterioration in air quality, which remains better than required by national standards. All reasonably foreseeable North Slope projects (see Table V-1a) would not change this situation. Considering that predicted discoveries and development from Alternative I for Sale 186 would represent only a few percent of the existing North Slope activity, air emissions from Alternative I, Sale 186 would have no significant contribution to cumulative effects for air quality.

Environmental Justice	
Effects Common to Alternatives I, III, IV, V, and VI for Sales 186, 195, and 202.	Sale-specific environmental justice effects would derive from potential noise, disturbance, and oil spill effects on subsistence resources, subsistence-harvest patterns, and sociocultural systems. The only substantial source of potential environmental justice-related effects to Native villages from the Beaufort Sea multiple sales and the range of alternatives would occur in the unlikely event of a large oil spill, which could affect subsistence resources. In the unlikely event that a large oil spill occurred and contaminated essential whaling areas, major effects could occur when impacts from contamination of the shoreline, tainting concerns, cleanup disturbance, and disruption of subsistence practices are factored together.
Cumulative Effects of Alternative I for Sale 186.	Potential effects would focus on the Inupiat communities of Barrow, Nuiqsut, and Kaktovik within the North Slope Borough; however, effects are not expected from routine activities and operations. If a large spill assumed in the cumulative case occurred and contaminated essential whaling areas, major effects could occur when impacts from contamination of the shoreline, tainting concerns, cleanup disturbance, and disruption of subsistence practices are factored together. Such impacts would be considered disproportionately high adverse effects on Alaskan Natives, because oil-spill contamination of subsistence foods is the main concern regarding potential effects on Native health. Any potential effects to subsistence resources and subsistence harvests are expected to be mitigated substantially, though not eliminated. Only in the event of a large spill, which is a low likelihood event, would disproportionate high adverse effects be expected on Alaska Natives from Alternative I for Sale 186.

Oil Spills	**See Table IV.A-5**		

Most of the information in this table may be found in Appendix B of this EIS.
[1] The figures presented in this table forecast activities beginning and ending in discrete time periods. This is done for the purpose of a consistent and methodical and based on a situational average. [2] Helicopter trips are expressed in an annual average. [3] Surface transport estimates vary according to the location of the exploration platform. Even if the exploration platform is located in the landfast-ice zone, surface transport volumes by ice road to the drill site will be less than half on the volumes forecast for a postfind construction phase. During the operations phase, vehicle trips could decline 100-200 per season. [4]An OCS block is 8.9 mi^2. [5]Helicopter support trips will decline sharply after the construction phase; however, Far Zone structures will consistently require greater levels of air support. [6] Marine support traffic for the construction phase will vary from 150-200 per open-water season for each nearshore platform to as many as 250 for structures beyond the landfast-ice zone. Vessel traffic will decline into the production phase, with 4-6 trips per season for nearshore platforms. [7]Based on a 90 day ice-road season. Estimates for Sale 195 are based on one platform in landfast ice zone. The platform assumed for Sale 202 will be beyond the landfast-ice zone. [8] The MMS's site-clearance seismic-survey requirements specify a minimum of 35 mi^2 (92 km^2) for a block-wide survey. Three days would be required for a 54 mi^2 site-clearance survey and 7 days for a 105 mi^2 survey. [9]The portrayed mileage is a rough estimate of a pipeline route from Smith Bay to the Kuparuk mainline. Should the pipeline landfall occur at Point Thomson, it would connect at the Badami field 12 miles distance. [10]Assuming 100,000 deadweight-ton tankers. Please note that all vessel trips inherently round trips. In reality, these periods may blend with and overlap each other. Estimates made in this table are speculative.

Table IV.A-5
Large, Small, and Very Large Spill Sizes We Assume for Analysis in this EIS by Section

EIS Section	Source of Spill	Type of Oil	Size of Spill(s) (Barrels)	Receiving Environment
Large Spills (≥1,000 barrels)				
—	**Offshore**	—	—	—
IV.C	Pipeline	Crude	4,600	Open Water
—	Platform/Gravel Island	Crude	1.500	Under Ice
—	Storage Tank	—	—	On Top of Sea Ice
—	—	—	—	Broken Ice
Small Spills (< 1000 barrels)				
—	**Offshore and Onshore**	—	147-184 spills <1 barrel[1]	Gravel Island
IV.C	Operational Spills	Diesel or	48-59 spills ≥1 barrel but <25 barrels	Open Water
—	from All Sources	Crude	3 spills >25 and <500 bbl	On Top of Sea Ice
—	—	Crude	0 spills >500 and <1,000 bbl	—
—	**Onshore and Offshore**	—	—	Broken Sea Ice
—	—	Refined	157-202 spills of 0.7 barrels each	Snow/Ice
—	—			Tundra
Very Large Spills (≥150,000 barrels)				
—	—	—	—	Open Water
IV.I	**Blowout from the Gravel Island**	Crude	180,000	On Top of Sea Ice
—	—	—	—	Broken Sea Ice

Source: USDOI, MMS, Alaska OCS Region (2001).
Notes:
Calculated with the Sintef oil-weathering model Version 1.8 of Reed et al. (2000) and assuming an Alaska North Slope crude type. For the Alternative I Sales 186, 195, and 202 and their alternatives, the median pipeline spill is assumed to be 4,600 barrels.

1 Summer (July through September), 12-knot wind speed, 2 degrees Celsius, 0.4-meter wave height.

2 Meltout Spill. Spill is assumed to occur in May into first-year pack ice, pools 2-centimeter thick on ice surface for 2 days at 0 degrees Celsius prior to meltout into 50% ice cover, 11-knot wind speed, and 0.1 meter wave heights.

3 This is the area of oiled surface.

4 Calculated from Equation 6 of Table 2 in Ford (1985) and is the discontinuous area of a continuing spill or the area swept by an instantaneous spill of a given volume. Note that ice dispersion occurs for about 30 days before meltout.

5 Calculated from Equation 17 of Table 4 in Ford (1985) and is the results of stepwise multiple regression for length of historical coastline affected.

Table IV.B-1
Essential Fish Habitat Ranking for Alternatives

	Freshwater Rank	Estuary Rank	Marine Rank	Composite Rank	Composite if Freshwater Weighted
No Lease Sale (II)*	1	1	1	1	1
Barrow Subsistence Whaling Deferral (III)	5	4	4	5	5
Nuiqsut Subsistence Whaling Deferral (IV)	2	3	3	3	2
Kaktovik Subsistence Whaling Deferral (V)	4	5	5	4	4
Eastern (VI)	3	2	2	2	3
Full Sale, No Deferral	6	6	6	6	6

*****While Alternative II would lower potential effects in the Beaufort Sea, those effects would be transferred to another location (see Section IV.C.2).

USDOI, MMS, "Arctic IMPAK: 1st Step Model" and "Arctic IMPAK: 2nd Step Model"
(a) NSB: North Slope Borough for place of residence meaning villages in the NSB but not in the OCS worker enclave or enclaves.
(b) Southcentral includes Municipality of Anchorage, Matanuska-Susitna Borough, and Kenai Peninsula Borough. Fairbanks means the Fairbanks Northstar Borough.

Table IV.I-1
Discharge Conditions for a Well Blowout to Open Water or Solid Ice

Discharge Category	Volume of Oil (Barrels)				
	Day 1	Day 2	Day 3	Day 15	15-Day Totals
Well's Discharge Volume	15,000	15,000	15,000	15,000	225,000
Evaporation (20%)	-3,000	-3,000	-3,000	-3,000	-45,000
Fall out to Gravel Island	6000	6,000	6,000	6,000	90,000
Oil Remaining on Gravel Island	-3,400	0 [1]	0 [1]	0 [1]	-3,400
Oil Draining to the Sea from Gravel Island	2,600	6000	6,000	6,000	86,600
Oil Falling to the Sea or Solid Ice	6,000	6,000	6,000	6,000	90,000
Total Oil to the Sea or Solid Ice	8,600	12,000	12,000	12,000	176,600

Notes: Assumes Alaska North Slope crude; constant wind speed of 20 knots; winds change from west-southwest to east-northeast; current speed of 0.6 knots; wave height of 1-5 feet; and air temperature of 45 °F.
[1] After hour 14, the gravel island is saturated with oil. All oil falling on the gravel island drains to the sea.

Notes:
Field information is taken from State of Alaska, Dept. of Natural Resources (2000).
Footnotes for Satellites identify the associated production unit:
[1]Duck Island Unit;
[2]Kuparuk River Unit;
[3]Milne Point Unit;
[4]Prudhoe Bay Unit.
Parentheses indicate when production startup is expected.
Definitions: Field—infrastructure (pads/wells/facilities) installed to produce one or more pools.
Satellite—a pool developed from an existing pad.
Pool—petroleum accumulation with defined limits.
Prospect—a discovery tested by several wells.
Show—a one-well discovery with poorly defined limits and production capacity.

Table V-1b
Trans-Alaska Pipeline System and Future Natural Gas Projects

Name	Estimated Pipeline Length (miles)	Project Description and Route
		Active Project
Trans-Alaska Pipeline (TAPS)	800	The TAPS is the key transportation link for all North Slope oil fields. It has been in operation since 1977 and to date, has carried nearly 13 billion barrels of oil. Approximately 16.3 square miles are contained in the pipeline corridor that runs between Prudhoe Bay and Valdez. The Dalton Highway (or Haul Road) was constructed parallel to the pipeline between Prudhoe Bay and Fairbanks. The pipeline design capacity is 2 million barrels per day, and it reached near peak capacity in 1988. Presently, the TAPS is running at about 1.0 million barrels per day. The lower operational limit generally is thought to be between 200,000 and 400,000 barrels per day. If oil production from northern Alaska cannot be sustained above this minimum rate, the TAPS will become nonoperational, and all oil production is likely to be shut in.
		Future Natural Gas Projects
Trans-Alaska Gas System (TAGS)	800	The TAGS plan consists of a gas-conditioning plant on the North Slope; an 800-mile, 42-inch, pipeline; a liquefied natural gas (LNG) plant and marine terminal at Valdez; and a fleet of new LNG carriers. LNG would be transported to Japan and other Pacific Rim countries. The Yukon Pacific Corporation has obtained permits for construction of the TAGS and export of Alaska North Slope gas to Asia. The LNG facility and marine terminal in Valdez has received the final EIS prepared by the Federal Energy Regulatory Commission. Yukon Pacific believes the large scale of the project (2.05 billion cubic feet per day to yield 14 million metric tons of LNG annually) will make this project competitive with other new LNG projects. The project currently is stalled by the lack of commitments from the North Slope gas producers, delivery contracts to Asian buyers, and high construction costs.
Alaska Natural Gas Transportation System (ANGTS)[1]	2,102	The ANGTS plan is a pipeline system connecting Alaska North Slope gas production through Canada to the lower 48. The new pipeline would run parallel to the TAPS from the North Slope to interior Alaska and then cross the Yukon Territory to connect to existing pipelines in Alberta. The primary market would be consumers in the U.S. Numerous permits, rights-of-way, and approvals have been obtained for the proposed pipeline route through Alaska and Canada. Downward revisions to construction costs and the recent increase in gas prices into the $3-$4-million/cubic-foot range make this project more appealing today. Currently, several variations to routes are being considered for the overland gas-pipeline system.
Arctic Resources, Northern Gas Pipeline Project	326 offshore 874 onshore	This project involves a 52-inch, high-pressure gas pipeline running offshore from Prudhoe Bay in Alaska to the Mackenzie Delta in Northwest Territory and then south through the Mackenzie River Valley to the existing gas pipeline network in northern Alberta. The 326-mile offshore portion would be trenched in 30-60 feet of water. The 874-mile onshore portion also would be buried. It is expected to deliver 2.5 billion cubic feet per day to markets primarily in the U.S. The project would involve a consortium of gas producers, pipeline companies, and Native Corporations in both Alaska and Canada. Commitments of gas producers and gas buyers have not yet been obtained; right-of-way permits also have not been issued.
Natural Gas to Liquids Conversion[2]	Will use existing TAPS pipeline	Atlantic Richfield Co. (ARCO) and Syntroleum Corp constructed a pilot-scale, natural gas to liquids (GTL) conversion facility in Puget Sound, Washington. More recently, BP-Amoco has begun design work on a GTL pilot project on the Kenai Peninsula in Alaska. As a result of the BP-Amoco-ARCO merger, BP-Amoco now holds an equal interest in the gas reserves in the Prudhoe Bay field. All of the major North Slope gas owners (BP-Amoco, Exxon-Mobil, and Phillips-Alaska) are studying the feasibility of various gas-commercialization projects. GTL is an attractive option because it will use the existing TAPS pipeline (extending its life and lowering future tariffs) and produce clean-burning fuels to meet more stringent Environmental Protection Agency emission standards for vehicles. At the present time, the overall cost of a full-scale gas to liquids project is comparable to a similar sized LNG project. As an emerging technology, new cost-reduction breakthroughs are expected for gas to liquids processing, improving the economic potential for future gas to liquid projects.

Northwest NPR-A	To Be Determined	As much as 9.98 million acres of the Northwest NPR-A Planning Area (*Federal Register*, 2001d).	To Be Determined
State Of Alaska			
North Slope Areawide	Oct. 2002, Oct. 2003, Oct. 2004, Oct. 2005	As much as 5,100,000 acres of State-owned lands between the Canning and Colville rivers and north of the Umiat Baseline (about 69° 20' N.).	*Moderate to High*
Beaufort Sea Areawide	Oct. 2002, Oct. 2003, Oct. 2004, Oct. 2005	Unleased State-owned tide- and submerged lands between the Canadian border and Point Barrow and some coastal uplands acreage located along the Beaufort Sea between the Staines and Colville rivers. The gross proposed sale area is in excess of 2,000,000 acres. The State of Alaska was scheduled to hold its first areawide sale in the Beaufort Sea on October 13, 1999. This sale was delayed pending the outcome of the British Petroleum-Amoco and ARCO merger and related uncertainties in future lease holdings.	*Moderate to High*
North Slope Foothills Areawide	May 2002	State-owned lands lying between the National Petroleum Reserve-Alaska and the Arctic National Wildlife Refuge south of the Umiat Baseline and north of the Gates of the Arctic National Park and Preserve. The gross proposed sale area is in excess of 7,000,000 acres.	*Moderate*

Note:
Bbbl = billion barrels.

Notes:

[1] Production information is from State of Alaska, Oil and Gas Conservation Commission (2002)
[2] Reserves were estimated by subtracting 2000 production from State of Alaska, Oil and Gas Conservation Commission (2001) from the Reserve Data in State of Alaska, Dept. of Natural Resources (2001,2002). Reserve estimates for Aurora, Borealis, Meltwater, and Polaris are from *PI/Dwight's Drilling Wire* (2001a, 2002, 2001b, and 2001c), respectively.
[3]Endicott includes Endicott, Sag Delta and Sag Delta North.
[4] Cascade is included in Milne Point.

Source: USDOI, MMS, Alaska OCS Region.

Notes:
Resource estimates are assumed for purposes of cumulative-effects analysis only. Accurate oil volumes for individual fields generally are unavailable, as these discoveries have not been adequately delineated or studied for their development potential. Most of these discoveries presently are noncommercial and will require new technology or higher oil prices to be economic. It is possible that many of these pools will remain undeveloped. Future development likely would occur in conjunction with the infrastructure for the fields shown in parentheses.

Resource estimates for Hemi Springs and Ugnu are not included in the above table, but they are included in the 2.0 billion barrels expected to be produced from satellites, pools, and enhanced recovery in existing fields. Gas resources are not listed because commercial production from the North Slope will require a new gas-transportation system to reach outside markets.

The oil volume including the Point Thompson pool is largely condensate recovered with associated gas-production wells. We assume that produced gas will be used for field operations (fuel) or be reinjected into reservoirs in nearby oil fields to optimize oil production. Reinjected gas could be recovered at some later date, when a transportation system for North Slope gas is constructed.

Table V-6b
Reasonably Foreseeable Future Development: Estimated New Infrastructure for Purposes of Analysis

Area/Group	Pads	Footprint (Acres)	Wells	Production Facilities	Base Camps	Docks	Airstrips	Roads	Pipeline (Miles)
NPR-A									
Western	4	120	131	1	1	1	0	0	38
Central	3	60	87	0	0	0	0	0	22
Eastern	10	316	343	6	4	2	3	12	131
Southern	1	25	20	0	0	0	0	12	12

Source: USDOI, MMS, Alaska OCS Region.

Notes:
Development Assumptions: (1) Industry will minimize permanent (gravel) roads by using ice roads; (2) new pipelines from satellite fields will tie into pipelines from main fields (Alpine, Northstar, Badami, Kuparuk River); (3) number of pads and wells are estimated from resource volumes; (4) production pad footprints are estimated from pad number, connecting roads, landfall/docks, and airstrips. Hemi Springs and Ugnu are considered to be examples of satellites and enhanced oil recovery, respectively, and will be developed using existing infrastructure of the Prudhoe Bay and Kuparuk River fields.

Table V-7a
Oil and Gas Production 1969 to December 2001 on the North Slope of Alaska

Production To Date	Oil (billions of barrels)	Gas (billions of cubic feet)	Reference
Onshore	13.256	342.24[1,2]	State of Alaska, AOGCC (2002)
Offshore	0.429	0	
Total	**13.625**	**40.24**	

Source:
USDOI, MMS, Alaska OCS Region.

Table V-7b
Summary of Reserve and Resource Estimates We Use for Analytical Purposes in the Cumulative Analysis

Production Activity	Oil (billions of barrels)	Contribution of Sale 186 by Volume of Oil (%)	Reference Table
Low End of the Range (Past and Present)	6	7.66	Table V.B-7c
Middle Portion (Past, Present, and Reasonably Foreseeable)	12	3.80	Table V.B-7c
High End (Past, Present, Reasonably Foreseeable, and Speculative)	15	3.07	Table V.B-7c

Source:
USDOI, MMS, Alaska OCS Region.
Sales 195 and 202 with similar resource estimates of 0.460 billion barrels would each contribute 3.80% by volume of oil.

Table V-7c

Total	**14.642**	**32,833**	Tables V.B-1a to 7b

Source:
USDOI, MMS, Alaska OCS Region.
Notes: Production and Reserve Data as of December 2000.
[1]Gas production to date is from Barrow gas fields supplied for local use to the village of Barrow. [2]Currently, all gas production from existing oilfields is consumed by facilities or reinjected for reservoir pressure maintenance. No gas production is transported and marketed outside of the North Slope. [3]Future production of natural gas assumes that a transportation system eventually will be constructed to move North Slope gas resources to outside markets. All proposed systems are uneconomic under current conditions. [4]Includes 2.0 billion barrels in unnamed satellite fields and from enhanced oil recovery from existing oil fields. Also, 0.300 and 0.370 billion barrels estimated for NE and NW NPR-A multiple sales respectively. [5a] Includes 60% of the mid-point undiscovered resources between the base case ($18.00) and high case ($30.00) of MMS's 2000 Assessment of Beaufort Sea. [5b]Includes the remaining portion (40%) of the mid-point undiscovered offshore resources recoverable between $18.00 and $30.00 per barrel.

Table V-7d
Estimates for Speculative Oil and Gas Resources

Area	Oil (billions of barrels)	Gas (trillions of cubic feet)	Study/Source
Beaufort Shelf	1.8–3.2	—	USDOI, MMS (2000)[1]
Northern Alaska	0.6–3.3	—	U.S. Geological Survey (1995)[2]
Beaufort-MacKenzie River Delta	1.0	9.0	National Energy Board (1998)[3]
Northeast NPR-A	0.5–2.2	—	USDOI ,BLM and MMS (1997)[4]
Arctic National Wildlife Refuge	2.4–6.3	—	U.S. Geological Survey (1998)[5]
North Slope-State lands	4.0	32.8	Industry[6]; MMS[7]
Chukchi Shelf	1.0–6.1	—	USDOI, MMS (2000)[1]

Notes:
The resource estimates for the Beaufort Shelf (USDOI, MMS, 2000)[1] and Northern Alaska (U.S. Geological Survey, 1995)[2] are mean undiscovered volumes that are economically recoverable at oil prices between $18 and $30 per barrel. Economic resources represent a small fraction of the total recoverable petroleum endowment, much of which is in pools too small or too remote to be economic under modeling assumptions. It is impossible to accurately predict the timing of commercial discoveries or future production volumes for speculative resources. Resource estimates often change with new information or modeling assumptions. For example, a new Geological Survey assessment (1998)[5] reports that more economic oil may occur in the small coastal plain of the Arctic National Wildlife Refuge than previously estimated (U.S. Geological Survey, 1995) for all of Northern Alaska. The economic analysis in Section III.D.5, including Table III.D-5, uses $16 per barrel price for the Proposal. The estimates shown use $18-$30 as reference prices. Assuming different price ranges are reasonable given the volatility of oil prices, a more optimistic assumption, that is a higher price, is reasonable for the cumulative case.
For the Liberty Proposal, exploration/appraisal is completed and the field is ready for development. For the cumulative case, regional exploration in Arctic Alaska is not complete and development may be delayed long into the undetermined future. The hope for giant oil fields will continue to draw leasing and exploration activities in the future. However, it is unreasonable to speculate on the timing and infrastructure needed to produce resources that have not been discovered. More than 30 trillion cubic feet of gas has been discovered on the North Slope and remains undeveloped due to the lack of a regional transportation infrastructure and market. This huge proven resource base undoubtedly will be produced before major exploration efforts are focused on undiscovered gas resources in other onshore areas or the Beaufort Sea off Alaska.

Marine	132 round trips	N/A	None	5-6 round trips Yearly	N/A	None
Badami[6]						
Aircraft	See footnote [6]	See footnote [6]	See footnote [6]	36 round trips weekly during drilling[7]	40 round trips weekly during drilling[7]	2 round trips weekly during drilling [7]
Surface	See footnote [6]	See footnote [6]	See footnote [6]	1 round trip yearly[8]	N/A	30 round trips daily during drilling [9]
Marine	See footnote [6]	See footnote [6]	See footnote [6]	10[10]	N/A	N/A

Notes:
[1]For the Alpine Project, summer is defined as April 20 to November 30; the rest of the year is winter. Alpine construction and development drilling phase may last from the present to approximately 2005, with the field life estimated at another 15-20 years.
[2]Aircraft operations calculated for the Alpine Project by Arco contractors were made on the basis of an amalgamation of three aircraft types: Hercules cargo plane, Twin Otter, and Boeing 737.
[3]The Northstar project should be completed (island construction and development drilling) within 4 years of initiation. The life of the field is projected at 15-20 years. The transportation requirements indicated here are the construction of the Northstar island in a single season.
[4]Data presented in the Northstar Final EIS (U.S. Army Corps of Engineers, 1999) for helicopter transport is not separated out by season.
[5]Data presented in the Northstar Final EIS for surface transport is not separated out by season. However, of the presented figure of 35,013 surface transport round trips, 2,775 round trips are bus trips and would be involved primarily with the movement of personnel to construction sites. The balance of the surface transport trips are by truck.
[6]The Badami project has proceeded beyond the construction phase and is now in developmental drilling.
[7]For all three periods, 6 aircraft operations will occur weekly after drilling.
[8]Planned pipeline inspection via rolligon; emergency use of rolligons not estimated.
[9]After drilling, 3 yearly round trips planned for pipeline inspection via rolligons; emergency use not estimated.
[10]An additional 10 round trips are planned in summer of 1998 to support drilling operations.

10.0	4,265,395	7,108,992	14,217,984	28,435,968

Notes:
Assumptions:
– 6-inch total road thickness.
– 2/3 of thickness is fresh water.
– 1/3 of thickness is snow.
– Typical tundra topography.
– 20% contingency for topographic feature correction, (i.e., stream ramps, etc.).
– Water volumes are calculated for construction only.
– No additional water included for ice road maintenance.

Table V-11
Summary of Cumulative Effects

Resources	Summary of Effects
a. Water Quality	A large crude or refined oil spill (greater than or equal to 500 barrels) would have a significant effect on water quality by increasing the concentration of hydrocarbons in the water column to levels that greatly exceed background concentrations; however, the chance of a large spill occurring is low. Also, regional (more than 1,000 square kilometers – 386 square miles), long-term (more than 1 year) degradation of water quality to levels above State and Federal criteria because of hydrocarbon contamination is very unlikely. Resuspended sediments from construction activities are not expected to exceed acute water-quality criteria and permitted discharges will be designed to ensure rapid mixing and dilution of the discharge. The effects from Sale 186 from construction activities are expected to be short term, lasting as long as the individual activity, and have the greatest impact in the immediate vicinity of the activity.
b. Lower Trophic Organisms	Effects of additional drilling discharges, construction-related activities and oil spills are not expected to substantially affect organisms in the Sale 186 area. Sale 186 is not expected to make a measurable contribution to the cumulative effects on these organisms.
c. Fishes	Small numbers of fish in the immediate area of an offshore or onshore oil spill may be killed or harmed, but this would not have a measurable effect on fish populations. Marine and migratory fishes are widely distributed in the Beaufort Sea and are not likely to be affected by the Sale 186. Oil is not expected to contact overwintering areas during winter. Hence, the Sale 186 is not expected to contribute measurably to the overall cumulative effect on fishes.
d. Essential Fish Habitat	Effects on essential fish habitat could result in a decrease in the time to extinction of any marginal salmon populations using freshwater or estuarine habitat.
e. Endangered Species: **Bowhead Whale** **Spectacled Eider** **Steller's Eider**	Bowhead whales may avoid noise-producing activities temporarily. Contact with spilled oil could cause temporary, nonlethal effects in bowheads, and a few could die from prolonged exposure to freshly spilled oil. The Sale 186 contribution to cumulative effects is expected to be limited to temporary avoidance behavior by a few bowhead whales in response to vessel traffic. Disturbance from support activities could cause displacement of spectacled eiders to less favorable areas. Frequent cumulative disturbance effects may cause declines in fitness, survival, or productivity. Collision of eiders with structures is expected to result in the loss of some individuals. Currently declining trend may slow recovery of the regional eider population from cumulative small losses or decline in fitness or productivity. Sale 186 effects would be additive to effects from all projects, but only in the case of substantial mortality from a large offshore oil spill would it be expected to raise cumulative effects to a significant level. Recovery from substantial oil spill mortality is not expected to occur while the population exhibits a declining trend. Oil transport through the Gulf of Alaska is expected to contribute little to cumulative effects on wintering Steller's eiders.
f. Marine and Coastal Birds	Disturbance from support activities could cause displacement of loons, waterfowl, and shorebirds to less favorable foraging areas. Frequent cumulative disturbance effects may cause declines in fitness, survival, or productivity. Collision of birds with structures is expected to result in the loss of some individuals. Currently declining trends in long-tailed duck and common eider populations may slow their recovery from cumulative small losses or decline in fitness or productivity. Sale 186 effects all bird species would be additive to effects from all projects, but only in the case of substantial mortality on regional long-tailed duck and common eider populations from a large offshore oil spill would it be expected to raise cumulative effects to a significant level. Any tanker spill in the Gulf of Alaska could cause substantial losses of migrating shorebirds and waterfowl that use Beaufort Sea habitats, or of overwintering loons, sea ducks, and gulls.
g. Maine Mammals (Pinnipeds, Polar Bears, Beluga and Gray Whales)	Ongoing activities that may effect pinnipeds, polar bears beluga, and gray whales include noise and disturbance, habitat alteration, and potential oil spills. Overall effects (mainly from oil) should last one year. Noise and disturbance, and habitat alteration could briefly and locally disturb or displace a few seals, walruses, polar bears, beluga and gray whales. A few polar bears could be temporarily attracted to the production island with no significant effects on the population's distribution and abundance.
h. Terrestrial Mammals	Oil development in the Prudhoe Bay area is likely to continue to displace some caribou during the calving season within about 4 kilometers of roads with vehicle traffic. Sale 186 is expected to contribute less than 4% of the local short-term disturbance of caribou. Cumulative development could briefly and locally disturb or displace a few muskoxen, grizzly bears and arctic foxes.
i.. Vegetation-Wetland Habitats	Construction causes more than 99% of the effects, with spills having a very minor role. Rehabilitation of gravel pads can result in the growth of grasses-sedges within 2 years after abandonment of the pads. Natural growth of plant cover would be very slow. Sale 186 would contribute less than 4% of the cumulative disturbance effects on 9,000 acres now affected by oil development.

Table V-11:
Summary of Cumulative Effects (continued)

Resources	Summary of Effects
j. Economy	This cumulative case likely would generate the following additive annual revenues: • $15 million to the North Slope Borough • $90 million to the State • $125 to the Federal Government This cumulative case likely would generate additive employment and personal income increases as follows: • 160 jobs annual average for North Slope Borough residents during development declining to 40 during production. These include direct oil industry employment, indirect and induced employment. • $10 million in total average annual personal income for workers residing in the North Slope Borough during development and declining to $2.8 million during production. • 5,800 jobs annual average during development declining to 3,300 during production. These jobs are for workers on the North Slope who reside in Southcentral Alaska and the Fairbanks. These include direct oil industry employment and indirect and induced employment. • $367 million in total average annual personal income for workers residing in Southcentral Alaska and Fairbanks during development declining to $211 million during production. • 5,800 jobs annual average during development declining to 3,300 during production. These jobs are for workers who reside in the rest of the U.S. These include indirect and induced employment generated by expenditure for goods and services used on the North Slope and spending by direct employees. • $367 million in total average annual personal income for workers residing in residing in the rest of the U.S. during development declining to $211 million during production. This income is for indirect and induced workers generated by expenditure for goods and services used on the North Slope and spending by direct employees. • 60-190 jobs for 6 months for cleanup of unlikely oil spills in the Beaufort Sea. • 10,000 jobs and 25% price inflation for 6 months for cleanup of an unlikely tanker oil spill in the Gulf of Alaska.
k. Subsistence-Harvest Patterns	In the past, drilling and seismic activity near the bowhead whale migration route has made subsistence whaling more difficult, and if a large oil spill occurred, subsistence harvests in Barrow, Nuiqsut, and Kaktovik could be affected with one or more important subsistence resources becoming unavailable or undesirable for use for 1-2 years, a significant adverse effect. Sale 186 is expected to have periodic effects on subsistence resources, but no harvest areas would become unavailable for use and no resource population would experience an overall decrease.
l. Sociocultural Systems	Past and present development of oil and gas and other projects have had negative effects on North Slope communities by producing conflicts to traditional lifestyles and straining social and health service providers. At the same time, tax revenues from past oil and gas development have also produced positive effects that include increased funding for infrastructure, higher incomes (that can be used to purchase better tools for subsistence), better health care, and improved educational facilities. Sale 186 development could produce periodic disturbance effects to communities but would not displace any sociocultural systems, community activities, or traditional practices.
m. Archaeological Resources	Sale 186's contribution to cumulative effects and the cumulative effects overall are expected to be minimal for archaeological resources, because any surface-disturbing activities that could damage archaeological sites would be mitigated by current State and Federal procedures.
n. Land Use Plans/CMP	Exploration and development and production can proceed consistent with the enforceable policies of the Alaska CMP and the North Slope Borough CMP. Requirements of the enforceable policies and standards can be effectively addressed through MMS regulatory oversight and the use of lease stipulations.
o. Air Quality	Projects in the past and present now have caused essentially no deterioration in air quality or contribute measurably to global climate change. Air emissions from the Sale 186 essentially would have no effects on air quality.
p. Environmental Justice	Alaska Inupiat Natives are a recognized minority and are potentially the most affected by Sale 186. Effects could occur to the communities of Nuiqsut and possibly Kaktovik. Effects are not expected from routine activities, but could occur from a large oil spill, although not from Sale 186. Oil-spill contamination of the essential whaling area and subsistence foods are the main concerns. Any potential effects to subsistence resources and subsistence harvests are expected to be mitigated substantially, though not eliminated.

Table V-12
Cumulative Oil-Spill-Occurrence Estimates ≥500 Barrels or ≥1,000 Barrels Resulting from Oil Development over the Assumed 15-20 Year Production Life of Sale 186

Category	Crude-Oil Spills

The complete EIS is available on CD-ROM (**MMS 2003-001 CD**) and on the Internet (**http://www.mms.gov/alaska/cproject/Beafort Sea/**).

This Environmental Impact Statement (EIS) is not intended, nor should it be used, as a local planning document by potentially affected communities. The exploration, development and production, and transportation scenarios described in this EIS represent best-estimate assumptions that serve as a basis for identifying characteristic activities and any resulting environmental effects. Several years will elapse before enough is known about potential local details of development to permit estimates suitable for local planning. These assumptions do not represent a Minerals Management Service recommendation, preference, or endorsement of any facility, site, or development plan. Local control of events may be exercised through planning, zoning, land ownership, and applicable State and local laws and regulations.

With reference to the extent of the Federal Government's jurisdiction of the offshore regions, the United States has not yet resolved some of its offshore boundaries with neighboring jurisdictions. For the purposes of the EIS, certain assumptions were made about the extent of areas believed subject to United States' jurisdiction. The offshore-boundary lines shown in the figures and graphics of this EIS are for purposes of illustration only; they do not necessarily reflect the position or views of the United States with respect to the location of international boundaries, convention lines, or the offshore boundaries between the United States and coastal states concerned. The United States expressly reserves its rights, and those of its nationals, in all areas in which the offshore-boundary dispute has not been resolved; and these illustrative lines are used without prejudice to such rights.

The Information, Models and Assumptions We Use to Analyze the Effects of Oil Spills in this EIS

We analyze oil spills and their relative impact to environmental, economic, and sociocultural resource areas and the coastline, which could result from offshore oil exploration and development in the Beaufort Sea Planning Area. Predicting an oil spill is an exercise in probability. Uncertainty exists regarding the location, number, and size of oil spills and the wind, ice and current conditions at the time of a spill. Although some of the uncertainty reflects incomplete or imperfect data, a considerable amount of uncertainty exists simply because it is difficult to predict events 15-40 years into the future.

We make assumptions to analyze the effects of oil spills. To judge the effect of an oil spill, we estimate information regarding the type of oil, the source of an oil spill, the location and size of a spill, the chemistry of the oil, how the oil will weather, how long it will remain, and where it will go. We describe the rationale for these assumptions in the following subsections. The rationale for these assumptions is a mixture of project-specific information, modeling results, statistical analysis, and professional judgment. Based on these assumptions, we assume a spill occurs and then analyze its effects. After we analyze the effects of an oil spill, we consider the chance of an oil spill ever occurring.

A. Estimates of the Source, Type, and Size of Oil Spills

Table IV.A-5 show the source of a spill(s), type of oil, size of spill(s) in barrels, and the receiving environment we assume in our analysis of the effects of oil spills in this EIS for the Proposal and Alternatives and other analyses. The sources of spills are generically divided into platform or pipeline. The type of oil used in this analysis is Alaska North Slope crude. We divide spills into three sizes- small, large, and very large spills. Small spills are those less than 1,000 barrels. Large spills are greater than or equal to 1,000 barrels, and very large spills are greater than or equal to 150,000 barrels. Table IV.A-5 shows the EIS section where we analyze the effects of a large, small, and very large spill.

A.1. Source and Spill-Size Assumptions

The spill assumptions we use for large spills are based on the historic spill sizes from production in the Gulf of Mexico outer continental shelf (OCS) and what we believe is likely to occur. We estimate the likely large spill size based on the median spill size in the Gulf of Mexico. Small spills are based on the historic spill sizes from production on the onshore Alaska North Slope. Very large spill sizes are based on BPXA's estimates of the greatest possible discharge that could occur from a blowout in the Oil Discharge

Prevention and Contingency Plans for the Liberty Development Area and Northstar (BPXA, 2001, 2002). The State of Alaska requires this estimate for a response planning standard under 18 AAC.75.430.

A.1.a. Historical Crude Oil Spills Greater Than or Equal to 1,000 Barrels on the Outer Continental Shelf

The Gulf of Mexico OCS data show that the most likely location of a spill is from a pipeline or a platform. The median size of a crude oil spill greater than or equal to 1,000 barrels from a pipeline from 1985-1999 on the outer continental shelf is 4,600 barrels, and the average is 6,700 barrels (Anderson and LaBelle, 2000). The median spill size for a platform on the outer continental shelf over the entire record from 1964-1999 based on trend analysis is 1,500 barrels, and the average is 3,300 barrels (Anderson and LaBelle, 2000). For purposes of analysis we use the median spill size as the likely large spill size.

A.1.b. Historical Crude Oil Spills From Blowouts

We consider blowouts to be unlikely events. Blowout events are often equated with catastrophic spills; however, in actuality very few blowout events have resulted in spilled oil, and the volumes spilled are often small. All five of the blowout events greater than or equal to 1,000 barrels in the OCS database occurred between 1964 and 1970 (Table A.1-1a). Following the Santa Barbara blowout in 1969, amendments to the OCS Lands Act and implementing regulations significantly strengthened safety and pollution-prevention requirements for offshore activities. Well-control training, redundant pollution-prevention equipment, and subsurface safety devices are among the provisions that have been adopted in the regulatory program. From 1971-2000, 199 blowouts occurred on the OCS while drilling approximately 29,000 wells and producing 11.4 billion barrels of oil. Twenty eight of those 199 blowouts resulted in oil spills of crude or condensate with the amount of oil spilled ranging from less than 1 barrel to 200 barrels. The total volume spilled from those 28 blowouts is approximately 1,200 barrels. The volume spilled from blowouts was approximately 0.00001% of the volume produced. There were no spills greater than or equal to 1,000 barrels from blowouts in the last 30 years on the OCS.

The record for Alaska North Slope blowouts is not validated, but is presented as the best available information. There are two written reports regarding blowouts on the Alaska North Slope, Mallory (1998) and Fairweather (2000). Fairweather (2000) found 10 blowouts, 6 that Mallory had identified and 4 prior to 1974. Of the 10 blowouts, 9 were gas and 1 was oil. The blowout of oil in 1950 was unspectacular and could not have been avoided, because there were no casings of blowout preventors available (Fairweather, 2000). These drilling practices from 1950 would not be relevant today. A third study confirmed that no crude oil spills greater than or equal to 100 barrels from blowouts occurred from 1985-1999 (Hart Crowser, Inc., 2000). A recent report titled Blowout Frequency Assessment of Northstar (Scandpower, 2001) uses statistical blowout frequencies modified to reflect specific field conditions and operative systems at Northstar. This report concludes that the blowout frequency for drilling the oil-bearing zone is 1.5×10^{-5} per well drilled. This compares to a statistical blowout frequency of 7.4×10^{-5} per well (for an average development well). This same report estimates that the frequency of oil quantities per well drilled for Northstar for a spill greater than 130,000 barrels is 9.4×10^{-7} per well.

However unlikely a blowout may be, because it is a significant concern to the public, we analyze the effects of an 180,000-barrel spill in Section IV.I Low Probability, Very Large Oil Spill.

B. Behavior and Fate of Crude Oils

There is scientific and historical information about the behavior and fate of crude oil. We also make several assumptions about oil weathering to perform modeling simulations of oil weathering.

B.1. Processes Affecting the Fate and Behavior of Oil

Several processes alter the chemical and physical characteristics and toxicity of spilled oil. Collectively, these processes are referred to as weathering or aging of the oil and, along with the physical oceanography and meteorology, the weathering processes determine the oil's fate. The major oil-weathering processes are spreading, evaporation, dispersion, dissolution, emulsification, microbial degradation, photochemical oxidation, and sedimentation to the seafloor or stranding on the shoreline (Payne et al., 1987; Boehm, 1987; Lehr, 2001) (Appendix A-1, Figures A-1 and A-2).

The physical properties of a crude oil spill, the environment it occurs in, and the source and rate of the spill will affect how an oil spill behaves and weathers. Table A.1-1b shows the properties of Alaska North Slope crude oil.

The environment in which a spill occurs, such as the water surface or subsurface, spring ice-overflow, summer open-water, winter under ice, or winter broken ice, will affect how the spill behaves. In ice-covered waters, many of the same weathering processes are in effect; however, the sea ice changes the rates and relative importance of these processes (Payne, McNabb, and Clayton, 1991).

After a spill occurs, spreading and advection begin. The slick spreads horizontally in an elongated pattern oriented in the direction of wind and currents and nonuniformly into thin sheens (0.5-10 micrometers) and thick patches (0.1-10 millimeters) (Elliott, 1986; Elliott, Hurford, and Penn, 1986; Galt et al., 1991). In the cooler arctic waters, oil spills spread less and remain thicker than in temperate waters because of differences in the viscosity of oil due to temperature. This property will reduce spreading. An oil spill in broken ice would spread less and would spread between icefloes into any gaps greater than about 8-15 centimeters (Free, Cox, and Shultz, 1982).

The presence of broken ice tends to slow the rate of spreading (S.L. Ross Environmental Research Ltd. and D.F. Dickens Assocs. Ltd., 1987). Oil spilled beneath a wind-agitated field of pancake ice would be pumped up onto the surface of the ice or, if currents are slow enough, bound up in or below the ice (Payne et al., 1987). Once oil is encapsulated in ice, it has the potential to move distances from the spill site with the moving ice.

Evaporation results in a preferential loss of the lighter, more volatile hydrocarbons, increasing density and viscosity and reducing vapor pressure and toxicity (Mackay, 1985). Evaporation of volatile components accounts for 30-40% of crude loss, with approximately 25% occurring in the first 24 hours (Fingas, Duval, and Stevenson, 1979; National Academy of Sciences, 1985). The initial evaporation rate increases with increasing wind speeds, temperatures, and sea state. Evaporative processes occur on spills in ice-covered waters, although at a lower rate (Jordan and Payne, 1980). Fuel oils (diesel) evaporate more rapidly than crude, on the order of 13% within 40 hours at 23° Celsius, a larger overall percentage of diesel eventually will evaporate. Evaporation decreases in the presence of broken ice and stops if the oil is under or encapsulated in the ice (Payne et al., 1987). The lower the temperature, the less crude oil evaporates. Both Prudhoe Bay and Endicott crudes have experimentally followed this pattern (Fingas, 1996). Oil between or on icefloes is subject to normal evaporation. Oil that is frozen into the underside of ice is unlikely to undergo any evaporation until its release in spring. In spring as the ice sheet deteriorates, the encapsulated oil will rise to the surface through brine channels in the ice. As oil is released to the surface, evaporation will occur.

Dispersion of oil spills occurs from wind, waves, currents, or ice. Dispersion is an important breakup process that results in the transport of small oil particles (0.5 micrometers-several millimeters) or oil-in-water emulsions into the water column (Jordan and Payne, 1980; National Research Council, 1985). Droplets less than 0.5 millimeter rise slowly enough to remain dispersed in the water column (Payne and McNabb, 1985). The dispersion rate is directly influenced by sea state; the higher the sea state and breaking waves, the more rapid the dispersion rate (Mackay, 1985). The presence of broken ice promotes dispersion (Payne et al., 1987). Any waves within the ice pack tend to pump oil onto the ice. Some additional oil dispersion occurs in dense, broken ice through floe-grinding action. More viscous and/or weathered crudes may adhere to porous icefloes, essentially concentrating oil within the floe field and limiting the oil dispersion.

Dissolution results in the loss of soluble, low-molecular-weight aromatics such as benzene, toluene, and xylenes (National Research Council, 1985). The low-molecular weight aromatics, which are acutely toxic, rapidly dissolve into the water column. Dissolution, however, is very slow compared with evaporation; most volatiles usually evaporate rather than dissolve. Dissolved-hydrocarbon concentrations underneath a slick, therefore, tend to remain less than 1 part per million (Malins and Hodgins, 1981). Dissolved-hydrocarbon concentration can increase due to the promotion of dispersion by broken ice (Payne et al., 1987).

Emulsified oil results from oil incorporating water droplets in the oil phase and generally is referred to as mousse (Mackay, 1982). The measurable increases in viscosity and specific gravity observed for mousse change its behavior, including spreading, dispersion, evaporation, and dissolution (Payne and Jordan, 1988). The formation of mousse slows the subsequent weathering of oil. The presence of slush ice and turbulence promotes oil-in-water emulsions (Payne et al., 1987).

Most of the oil droplets suspended in the water column eventually will be degraded by bacteria in the water column or deposited on the seafloor. The rate of sedimentation depends on the suspended load of the water, the water depth, turbulence, oil density, and incorporation into zooplankton fecal pellets.

Subsurface blowouts or gathering-pipeline spills disperse small oil droplets and entrained gas into the water column. With sufficient gas, turbulence, and the necessary precursors in the oils, mousse forms by the time the oil reaches the surface (Payne, 1982; Thomas and McDonagh, 1991). For subsurface spills, oil rises rapidly to the water surface to form a slick. Droplets less than 50 microns in size, generally 1% of the blowout volume, could be carried several kilometers downcurrent before reaching the water surface (Environmental Sciences Limited, 1982). Blowout simulations show that convective cells set up by the rising oil and gas plume result in concentric rings of waves around the central plume. Surface currents within the ring should move outward, and surface currents outside the ring should move inward, resulting in a natural containment of some oil.

The subsurface release of oil droplets increases slightly the dissolution of oil, but the rapid rise of most oil to the surface suggests that the increase in dissolution—as a percentage of total spill volume—is fairly small. The resulting oil concentration, however, could be substantial, particularly for dispersed oil in subsurface plumes.

An oil spill under ice would follow this sequence: (1) The oil will rise to the under-ice surface and spread laterally, accumulating in the under ice cavities (Glaeser and Vance 1971; NORCOR, 1975; Martin, 1979; Comfort et al., 1983). (2) For spills that occur when the ice sheet is still growing, the pooled oil will be encapsulated in the growing ice sheet (NORCOR, 1975; Keevisl and Ramseier, 1975; Buist and Dickens, 1983; Comfort et al., 1983). (3) In the spring as the ice begins to deteriorate, the encapsulated oil will rise to the surface through brine channels in the ice (NORCOR, 1975; Purves, 1978; Martin, 1979; Kisil, 1981; Dickins and Buist, 1981; Comfort et al., 1983). The spread of oil under the landfast ice may be affected by the presence of currents, if the magnitude of those currents is large enough. A field study near Cape Parry in the Northwest Territories reported that currents up to 10 centimeters per second were present. This current was insufficient to strip oil from under the ice sheet after the oil had ceased to spread (NORCOR, 1975). Laboratory tests have shown that currents in excess of 15-25 centimeters per second are required to strip oil from under-ice depressions (Cammaert, 1980; Cox et al., 1980). Current speeds in the nearshore Beaufort generally are less than 10 centimeters per second during the winter (Weingartner and Okkonen 2001). The area of contamination for oil under ice could increase if the ice were to move. Because the nearshore Beaufort is in the landfast ice area, the spread of oil due to ice movement would not be anticipated until spring breakup.

Alaska North Slope crude oil will readily emulsify to form stable emulsions. Emulsification of some crude oils is increased in the presence of ice. With floe grinding, Prudhoe Bay crude forms a mousse within a few hours, an order of magnitude more rapidly than in open water.

B.2. Shoreline Type

The shoreline habitats and the estimation of the behavior and persistence of oil on intertidal habitats is based on an understanding of the dynamics of the coastal environments, not just the substrate type and grain size. The sensitivity of a particular intertidal habitat is an integration of the following factors: 1) shoreline type (substrate, grain size, tidal elevation, origin); 2) exposure to wave and tidal energy; 3) biological productivity and sensitivity; and 4) ease of cleanup. All of these factors are used to determine the relative sensitivity of intertidal habitats. Key to the sensitivity ranking is an understanding of the relationships between physical processes; substrate; shoreline type; product type; fate and effect; and sediment-transport patterns. The intensity of energy expended on a shoreline by wave action, tidal currents, and river currents directly affects the persistence of stranded oil. The need for shoreline cleanup activities is determined, in part, by the slowness of natural processes in removal of oil stranded on the shoreline. These concepts have been used in the development of the ESI, which ranks shoreline environments as to their relative sensitivity to oil spills, potential biological injury, and ease of cleanup. Generally speaking, areas exposed to high levels of physical energy, such as wave action and tidal currents, and low biological activity rank low on the scale, whereas sheltered areas with associated high biological activity rank highest. A comprehensive shoreline habitat ranking system has been developed for the entire United States. The shoreline habitats delineated on the North Slope of Alaska are listed in order of increasing sensitivity to spilled oil:
3A) Fine- to Medium-grained Sand Beaches
3C) Tundra Cliffs
5) Mixed Sand and Gravel Beaches
6A) Gravel Beaches
7) Exposed Tidal Flats
8B) Sheltered, Solid Man-made Structures
8E) Peat Shorelines
9A) Sheltered Tidal Flats
10A) Salt- and Brackish-Water Marshes
10E) Inundated Low-lying Tundra
U) Unranked

The ESI rankings progress from low to high susceptibility to oil spills. In many cases, the shorelines also are ranked with multiple codes such as 10E/7. The first number is the most landward shoreline type, saltmarsh, with exposed tidal flats being the shoreline type closest to the water. Table A.1-1c shows the percentage of each ESI ranking for the most seaward shoreline type for each land segment.

B.3. Assumptions about Oil Weathering

- The crude oil properties will be similar to Alaska North Slope crude (Table A.1-1b).
- The size of the spill is 1,500 or 4,600 barrels.
- The wind, wave, and temperature conditions are as described.
- Meltout spills occur into 50% ice cover.
- The properties predicted by the model are those of the thick part of the slick.
- The spill occurs as an instantaneous spill over a short period of time.

Uncertainties exist, such as:
- the actual size of the oil spill or spills, should they occur;
- whether the spill is instantaneous or chronic
- wind, current, wave, and ice conditions at the time of a possible oil spill; and
- the crude oil properties at the time of a possible spill.

B.4. Modeling Simulations of Oil Weathering

To judge the effect of an oil spill, we estimate information regarding how much oil evaporates, how much oil is dispersed and how much oil remains after a certain time period. We derive the weathering estimates of Alaska North Slope crude oil and arctic diesel from modeling results from the SINTEF Oil Weathering Model (OWM) Version 2.0 (Reed et al., 2000) for up to 30 days.

Tables IV.A-6a and 6b show the results for Alaska North Slope crude oil spills using the SINTEF model. The SINTEF OWM changes both oil properties and physical properties of the oil. The oil properties include density, viscosity, pour point, flash point, and water content. The physical processes include spreading, evaporation, oil-in-water dispersion, and water uptake. The SINTEF OWM Version 2.0 performs a 30-day time horizon on the model-weathering calculations, but with a warning that the model is not verified against experimental field data for more than 4-5 days. The SINTEF OWM has been tested extensively with results from three full-scale field trials of experimental oil spills (Daling and Strom, 1999).

The SINTEF OWM does not incorporate the effects of the following:

- currents;
- beaching;
- containment;
- photo-oxidation;
- microbiological degradation;
- adsorption to particles; and
- encapsulation by ice.

The Alaska North Slope crude oil spill sizes are 1,500 or 4,600 barrels. We simulate two general scenarios: one in which the oil spills into open water and one in which the oil freezes into the ice and melts out into 50% ice cover. We assume open water is July through September, and a winter spill melts out in July. For open water, we model the weathering of the 1,500 or 4,200-barrel spills as if they are instantaneous spills. For the meltout spill scenario, we model the entire spill volume as an instantaneous spill. Although different amounts of oil could melt out at different times, the MMS took the conservative approach, which was to assume all the oil was released at the same time. We report the results at the end of 1, 3, 10, and 30 days.

Tables IV A.6a and 6b summarize the results we assume for the fate and behavior of Alaska North Slope crude oil and diesel oil in our analysis of the effects of oil on environmental and social resources.

C. Estimates of Where an Offshore Oil Spill May Go

We study how and where large offshore spills move by using a computer model called the Oil-Spill-Risk Analysis model (Smith et al., 1982). By large, we mean spills greater than or equal to 1,000 barrels. This model analyzes the likely paths of oil spills in relation to biological, physical, and social resources. The model uses information about the physical environment, including files of wind, ice, and current data. It also uses the locations of environmental resource areas, barrier islands, and the coast that might be contacted by a spill.

C.1. Inputs to the Oil-Spill-Trajectory Model

- study area
- arctic seasons
- location of the coastline
- location of environmental resource areas
- location of land segments
- location of boundary segments
- location of hypothetical launch areas
- location of hypothetical pipelines and transportation assumptions
- current and ice information from two general circulation models
- wind information.

C.1.a. Study Area and Boundary Segments

Map A-1 shows the Beaufort multiple-sale oil-spill-trajectory study area extends from lat. 68º N. to 74º N. and from long. 134° W. to 176° W. The study area is formed by 38 boundary segments and the Chukchi and Beaufort Sea coastline. The boundary segments are vulnerable to spills in both arctic summer and winter. We chose a study area large enough to contain the paths of 2,700 hypothetical oil spills each through as long as 360 days.

C.1.b. Seasons

We define three time periods for the trajectory analysis of oil spills. The first is from July through September and represents open water or arctic summer. We ran 675 trajectories in the arctic summer. The second is from October through June and represents ice cover or arctic winter. We also ran 2,025 trajectories in the arctic winter. The last is annual, which is from January through December, and represents the entire year. We ran 2,700 trajectories.

C.1.c. Locations of Environmental Resource Areas

Maps A-2a, A-2b, A-2c and A-2d show the location of 88 environmental resource areas, which represent concentrations of wildlife, subsistence-hunting areas, and subsurface habitats. Our analysts designate these environmental resource areas. The analysts also designate in which months these environmental resource areas are vulnerable to spills. The names or abbreviations of the environmental resource areas and their months in which they are vulnerable to spills are shown in Table A.1-2a. We also include Land as an additional environmental resource area. Land is the entire study area coastline.

C.1.d. Location of Land Segments

Land was further analyzed by dividing the Beaufort Sea coastline into 66 land segments. Maps A-3a and A-3b show the location of these 66 land segments. Land segments are vulnerable to spills in both summer and winter. The model defines summer as July through September and winter from October through June. The land segment identification numbers (ID) and the geographic place names within the land segment are shown in Table A.1-2b. Some land segments were grouped as follows:

- Arctic National Wildlife Refuge — 43, 44, 45, 46, 47, 48, 49, 50, 51
- Ivvavik National Park — 52, 53, 54, 56, 57
- Hershel Island — 55
- Kendall Island Bird Sanctuary — 64, 65
- Teshekpuk Lake Special Use Area — 29, 30, 31, 32, 33

C.1.e. Location of the Proposed and Alternative Hypothetical Spill Areas and Pipeline Segments

Map A-4a shows the location of the 18 hypothetical launch areas and 13 pipeline segments, the sites where large oil spills would originate, if they were to occur. There are 735 spill points evenly spread over the 18 hypothetical launch areas and 13 pipeline segments. Hypothetical spills were started at the 735 spill points and 13 pipeline segments. With the exception of the Northstar pipeline, landfall locations were chosen based on educated guesses. For example the Liberty pipeline was chosen as a landfall. Since that time, the project has been canceled.

Map A-4b shows the location of the alternatives to indicate where spill areas and pipelines would be removed. It also shows the location of the Near, Midrange, and Far zones. Table A.1-3 shows the transportation assumptions for the spill areas and their associated pipelines.

Table A.1-4 shows how the pipelines and launch areas relate to the Near Zone, Midrange Zone, and Far Zone scenarios and each alternative for each sale. For Sales 186, 195, and 202 Alternative I, we assume no oil large spills occur during exploration activities. Development/production activities for Sale 186 are not expected to occur in the Far Zone, and there would be no spill from launch areas or pipeline segments in this zone (LA1-LA5, LA11, LA13-LA16, LA18, P1, P5, P6, and P8). Development/production activities for Sale 195 are not expected to occur in the Far Zone, and there would be no spill from launch areas or pipeline segments in this zone (LA1-LA5, LA11, LA13-LA16, LA18, P1, P5, P6, and P8). One development/production project is expected to occur in the Far Zone for Sale 202. No development/production projects are expected in the Near Zone or the Midrange Zone, and there would be no spill from launch areas LA8 and LA10.

C.1.f. Current and Ice Information from a General Circulation Model

For the Beaufort multiple-sale, we use two general circulation models to simulate currents ($U_{current}$) or ice (U_{ice}) depending upon whether the location is nearshore or offshore.

C.1.f.(1) Offshore

Offshore of the 10- to 20-meter bathymetry contour, the wind-driven and density-induced ocean-flow fields and the ice-motion fields are simulated using a three-dimensional, coupled, ice-ocean hydrodynamic model (Haidvogel, Hedstrom, and Francis, 2001). The model is based on the ocean model of Haidvogel ,Wilkin, and Young (1991) and the ice models of Hibler (1979) and Mellor and Kantha (1989). This model simulates flow properties and sea-ice evolution in the western Arctic during the years 1982-1996. The coupled system uses the S-Coordinate Rutgers University Model (SCRUM) and Hibler viscous-plastic dynamics and the Mellor and Kantha thermodynamics. It is forced by daily surface geostrophic winds and monthly thermodynamic forces. The model is forced by thermal fields for the years 1982-1996. The thermal fields are interpolated in time from monthly fields. The location of each trajectory at each time interval is used to select the appropriate ice concentration. The pack ice is simulated as it grows and melts. The edge of the pack ice is represented on the model grid. Depending on the ice concentration, either the ice or water velocity with wind drift from the stored results of the Haidvogel, Hedstrom and Francis (2001) coupled ice-ocean model is used. A major assumption used in this analysis is that the ice-motion velocities and the ocean daily flows calculated by the coupled ice-ocean model adequately represent the flow components. Comparisons with data illustrate that the model captures the first-order transport and the dominant flow (Haidvogel, Hedstrom and Francis, 2001).

C.1.f.(2) Nearshore

Inshore of the 10- to 20-meter bathymetry contour, $U_{current}$ is simulated using a two-dimensional hydrodynamic model developed by the National Oceanic and Atmospheric Administration (NOAA) (Galt, 1980, Galt and Payton, 1981). This model does not have an ice component. In this model, we added an ice mask within the 0-meter and 10- to 20-meter water-depth contours to simulate the observed shorefast-ice zone. We apply the mask from November 1-June 15 in the Beaufort and December 1 to May 1 in selected areas of the Chukchi. U_{ice} is zero for the months November through June or January to May. The two-dimensional model incorporated the barrier islands in addition to the coastline. The model of the shallow water is based on the wind forcing and the continuity equation. The model was originally developed to simulate wind-driven, shallow-water dynamics in lagoons and shallow coastal areas with a complex shoreline. The solutions are determined by a finite element model where the primary balance is between the wind forcing friction, the pressure gradients, coriolis accelerations, and the bottom friction. The time dependencies are considered small, and the solution is determined by iteration of the velocity and sea level equations, until the balanced solution is calculated. The wind is the primary forcing function, and a sea level boundary condition of no anomaly produced by the particular wind stress is applied far offshore, at the northern boundary of the oil-spill-trajectory analysis domain. An example of the currents simulated by this model for a 10-meter-per-second wind is shown in Appendix A-1,Figure A-3.

The results of the model were compared to current meter data from the Endicott Environmental Monitoring Program to determine if the model was simulating the first order transport and the dominant flow. The model simulation was similar to the current meter velocities during summer. Example time series from 1985 show the current flow at Endicott Station ED1 for the U (east-west) and V (north-south) components plotted on the same axis with the current derived from the NOAA model for U and V (Der-U and Der-V). The series show many events that coincide in time, and that the currents derived from the NOAA model generally are in good correspondence with the measured currents. Some of the events in the measured currents are not particularly well represented, and that probably is due to forcing of the current by something other than wind, such as low frequency alongshore wave motions.

C.1.g. Wind Information

We use 15 of the 17-year re-analysis of the wind fields provided to us by Rutgers. The TIROS Operational Vertical Sounder (TOVS) has flown on NOAA polar-orbiting satellites since 1978. Available from July 7, 1979, through December 31, 1996, and stored in Hierarchical Data Format, the TOVS Pathfinder (Path-P) dataset provides observations of areas poleward of lat. 60° N. at a resolution of approximately 100 x 100 kilometers. The TOVS Path-P data were obtained using a modified version of the Improved Initialization Inversion Algorithm (3I) (Chedin et al., 1985), a physical-statistical retrieval method improved for use in identifying geophysical variables in snow- and ice-covered areas (Francis, 1994). Designed to address the particular needs of the polar-research community, the dataset is centered on the North Pole and has been gridded using an equal-area azimuthal projection, a version of the Equal-Area Scalable Earth-Grid (EASE-Grid) (Armstrong and Brodzik, 1995).

Preparation of a basinwide set of surface-forcing fields for the years 1980 through 1996 has been completed (Francis, 1999). Improved atmospheric forcing fields were obtained by using the bulk boundary-layer stratification derived from the TOVS temperature profiles to correct the 10-meter level geostrophic winds computed from the National Center for Environmental Prediction Reanalysis surface pressure fields. These winds are compared to observations from field experiments and coastal stations in the Arctic Basin and have an accuracy of approximately 10% in magnitude and 20 degrees in direction.

C.1.h. Oil-Spill Scenario

For purposes of this trajectory simulation, all spills occur instantaneously. For each trajectory simulation, the start time for the first trajectory was the first day of the season (summer or winter) of the first year of wind data (1982) at 6 a.m. Greenwich Mean Time. We launch particles every 2 days (on average) for each of the 15 years of wind.

C.2. Oil-Spill-Trajectory Model Assumptions

- Oil spills occur in the hypothetical spill areas or along pipeline segments.
- Companies transport the produced oil through pipelines.
- An oil spill reaches the water.
- An oil spill encapsulated in the fast ice does not move until the ice moves or it melts out.
- Oil spills occur and move without consideration of weathering. The oil spills are simulated each as a point with no mass or volume. The weathering of the oil is estimated in the stand alone SINTEF OWM model.

- Oil spills occur and move without any cleanup. The model does not simulate cleanup scenarios. The oil-spill trajectories move as though no booms, skimmers, or any other response action is taken.
- Oil spills stop when they contact the mainland coastline, but not the barrier islands in Stefansson Sound.

Uncertainties exist, such as:
- the actual size of the oil spill or spills, should they occur;
- whether the spill reaches the water;
- whether the spill is instantaneous or a long-term leak;
- the wind, current, and ice conditions at the time of a possible oil spill;
- how effective cleanup is;
- the characteristics of crude oil at the time of the spill;
- how Alaska North Slope crude oil will spread; and
- whether or not production occurs.

C.3. Oil-Spill-Trajectory Simulation

The trajectory simulation portion of the model consists of many hypothetical oil-spill trajectories that collectively represent the mean surface transport and the variability of the surface transport as a function of time and space. The trajectories represent the Lagrangian motion that a particle on the surface might take under given wind, ice, and ocean-current conditions. Multiple trajectories are simulated to give a statistical representation, over time and space, of possible transport under the range of wind, ice, and ocean-current conditions that exist in the area.

Trajectories are constructed from simulations of wind-driven and density-induced ocean flow fields and the ice-motion field. The basic approach is to simulate these time- and spatially dependent currents separately, then combine them through linear superposition to produce an oil-transport vector. This vector is then used to create a trajectory. Simulations are performed for three seasons: winter (October-June), summer (July-September), and annual (January-December). The choice of this seasonal division was based on meteorological, climatological, and biological cycles and consultation with Alaska Region analysts.

For cases where the ice concentration is below 80%, each trajectory is constructed using vector addition of the ocean current field and 3.5% of the instantaneous wind field—a method based on work done by Huang and Monastero (1982), Smith et al. (1982), and Stolzenbach et al. (1977). For cases where the ice concentration is 80% or greater, the model ice velocity is used to transport the oil. Equations 1 and 2 show the components of motion that are simulated and used to describe the oil transport for each spillete:

1 $U_{oil} = U_{current} + 0.035\ U_{wind}$

or

2 $U_{oil} = U_{ice}$

where:

U_{oil} = oil drift vector

$U_{current}$ = current vector (when ice concentration is less than 80%)

U_{wind} = wind speed at 10 meters above the sea surface

U_{ice} = ice vector (when ice concentration is greater than or equal to 80%)

The wind-drift factor was estimated to be 0.035, with a variable drift angle ranging from 0º to 25º clockwise. The drift angle was computed as a function of wind speed according to the formula in Samuels, Huang, and Amstutz (1982). (The drift angle is inversely related to wind speed.)

The trajectories age while they are in the water and/or on the ice. For each day that the hypothetical spill is in the water, the spill ages—up to a total of 360 days. While the spill is in the ice (greater than or equal to 80% concentration), the aging process is suspended. The maximum time allowed for the transport of oil in the ice is 360 days, after which the trajectory is terminated. After coming out of the ice into open water, the trajectory ages to a maximum of 30 days.

C.4. Results of the Oil-Spill-Trajectory Model

C.4.a. Conditional Probabilities: Definition and Application

The chance that an oil spill will contact a specific environmental resource area or land or boundary segment within a given time of travel from a certain location or spill site is termed a conditional probability. The condition is that we assume a spill occurs. Conditional probabilities assume a spill has occurred and the transport of the spilled oil depends only on the winds, ice, and ocean currents in the study area.

For the Beaufort multiple-sales, we estimate conditional probabilities of contact within 1, 3, 10, 30, 60, 180, or 360 days during summer. Summer spills are spills that begin in July through September. Therefore, if any contact to an environmental resource area or land segment is made by a trajectory that began before the end of September, it is considered a summer contact and is counted along with the rest of the contacts from spills launched in the summer. We also estimate the conditional probability of contact from spills that start in winter, freeze into the landfast ice and meltout in the spring. We estimate contacts from these spills for 1, 3, 10, 30, 60, 180, or 360 days. Winter spills are spills that begin in October through June, melt out of the ice, and contact during the open-water period. Therefore, if any contact to an environmental resource area or land segment is made by a trajectory that began by the end of June, it is considered a winter contact and is counted along with the rest of the contacts from spills launched in the winter.

C.4.a.(1) Conditional Probabilities: Results

The chance of a spill contacting is taken from the oil-spill trajectory model results summarized below and listed in Tables A2-1 through A2-54 and A2-73 through A2-90.

C.4.a.(1)(a) Comparisons between Spill Location and Season

The primary differences of contact between spill locations are geographic in the perspective of west to east and nearshore versus offshore. Offshore spill locations take longer to contact the coast and nearshore environmental resource area, if contact occurs at all. Winter spill contact to nearshore and coastal resources is less often and to a lesser extent due to the landfast ice in place from October to June.

C.4.a.(1)(b) Generalities Through Time

3 Days: During summer, offshore launch areas 1, 7, 9, 11, 13, 14, and 16 have less than a 0.5% chance of contacting individual land segments within 3 days. Nearshore launch areas have a less than 0.5-6% chance of contacting individual land segments. Pipeline segments have a less than 0.5-14% chance of contacting individual land segments. Contacts to land segments from pipeline spills are highest where the pipeline comes ashore.

During summer, offshore launch areas 1 through 18 have a less than 0.5-46% chance of contacting individual environmental resource areas. Launch areas adjacent to or on top of environmental resource areas have the highest percent chance of contact. Pipeline segments 1 through 13 have a less than 0.5% to a greater than 99.5% chance of contact to individual environmental resource areas.

During winter, launch areas 1, 3, 5, 7, and 9 through 17 have a less than 0.5% chance of contacting individual land segments within 3 days. Nearshore launch areas 2, 4, 6, 8, and 18 have a less than 0.5-1% chance of contacting individual land segments. Pipeline segments have a less than 0.5-5% chance of contacting individual land segments.

During winter, offshore launch areas 1 through 18 have a less than 0.5-46% chance of contacting individual environmental resource areas. Launch areas adjacent to or on top of environmental resource areas have the highest percent chance of contact. Pipeline segments 1 through 13 have a less than 0.5% to greater than 99.5% chance of contact to individual environmental resource areas.

10 Days: During summer, offshore spill box 14 has less than a 0.5% chance and launch areas 9, 11, and 13 have a less than 0.5-1% chance of contacting individual land segments within 10 days. The other launch areas have a less than 0.5-13% chance of contacting individual land segments. Pipeline segments have a less than 0.5-18% chance of contacting individual land segments. Contacts to land segments from pipeline spills are highest where the pipeline comes ashore.

During summer, offshore spill boxes 1 through 18 have a less than 0.5-60% chance of contacting individual environmental resource areas. Launch areas adjacent to or on top of environmental resource areas have the highest percent chance of contact. Pipeline segments 1 through 13 have a less than 0.5% to greater than 99.5% chance of contact to individual environmental resource areas.

During winter, offshore launch areas 3, 9, 11, 13, 14, 15, and 16 have less than a 0.5% chance of contacting individual land segments within 10 days. Other launch areas have a less than 0.5-2% chance of contacting individual land segments. Pipeline segments have a less than 0.5-6% chance of contacting individual land segments.

During winter, offshore launch areas 1 through 18 have a less than 0.5% to greater than 59% chance of contacting individual environmental resource areas. Launch areas adjacent to or on top of environmental resource areas have the highest percent chance of contact. Pipeline segments 1 through 13 have a less than 0.5% to greater than 99.5% chance of contact to individual environmental resource areas.

30 Days: During summer, launch areas have a less than 0.5-17% chance of contacting individual land segments within 30 days. Pipeline segments have a less than 0.5-21% chance of contacting individual land segments. Contacts to land segments from pipeline spills are highest where the pipeline comes ashore.

During summer, offshore launch areas 1 through 18 have a less than 0.5-66% chance of contacting individual environmental resource areas. Launch areas adjacent to or on top of environmental resource areas have the highest percent chance of contact. Pipeline segments 1 through 13 have a less than 0.5% to greater than 99.5% chance of contact to individual environmental resource areas.

During winter, offshore launch areas 11, 13, and 14 have less than a 0.5% chance of contacting individual land segments within 30 days. Other launch areas have a less than 0.5-4% chance of contacting individual land segments. Pipeline segments have a less than 0.5-6% chance of contacting individual land segments.

During winter, offshore launch areas 1 through 18 have a less than 0.5% to greater than 62% chance of contacting individual environmental resource areas. Launch areas adjacent to or on top of environmental resource areas have the highest percent chance of contact. Pipeline segments 1 through 13 have a less than 0.5% to greater than 99.5% chance of contact to individual environmental resource areas.

D. Oil-Spill-Risk-Analysis

A measure of oil-spill impact is determined by looking at the chance of a spill occurring and then contacting a resource of concern. This analysis helps determine the relative spill occurrence and contact associated with oil and gas production in different regions of the proposed area. Combined probabilities are estimated using the conditional probabilities, the historical oil-spill rates, the resource estimates, and the assumed transportation scenarios. These are combined through matrix multiplication to estimate the mean number of spills occurring and contacting.

D.1. Chance of a Spill Occurring

The chance of a spill occurring is derived from two components: (1) the spill rate and (2) the resource volume estimates.

D.1.a. Spill Rates

We derive the spill rates from a modeling study done by the Bercha Group, Inc. (2002). This study examined alternative oil-spill-occurrence estimators for the Beaufort and Chukchi seas using a fault-tree method. During preparation of the Liberty Development final EIS, stakeholders expressed concern regarding the application of historical data from the Gulf of Mexico to the Beaufort OCS. For the Liberty Development final EIS, historical oil-spill data were gathered from a multitude of sources. Various causes of spills were looked at in relation to their relevance to arctic conditions. A preliminary assessment was made regarding the contribution of arctic versus non-arctic conditions. Because sufficient historical data on offshore oil spills for these regions do not exist for the Arctic on oil-spill occurrence, a model based on fault-tree methodology was developed and applied for this Beaufort multiple-sale EIS (Bercha Group, Inc., 2002). Using fault trees, oil-spill data from the Gulf of Mexico were modified and incremented to represent expected Arctic performance.

D.1.a.(1) Limitations of Input data

The Arctic effects include modifications in causes associated with the historical data set in addition to additions of spill causes unique to the arctic environment. Quantification of existing causes for the Arctic was done in a relatively cursory way restricted to engineering judgment. A reproducible but relatively elementary analysis of gouging and scour effects was carried out. Upheaval-buckling and thaw-settlement effect assessments were included on the basis of professional judgment; no engineering analysis was carried out for the assessment of frequencies to be expected for these effects. No Arctic effects were estimated for the wells, which were considered to blow out with frequencies the same as those for the Gulf of Mexico. The existing MMS databases on pipeline mileage were used as they stand with all their inherent inaccuracies.

D.1.a.(2) Results for Spill Rates

Based on the Bercha Group, Inc. (2002) fault-tree analysis for Sale 186, the MMS calculates the spill rates as follows:

Platforms	0.13 spills per billion barrels produced
Pipelines	0.10 spills per billion barrels produced

D.1.b. Source-Volume Estimates

The resource volume estimates are discussed in terms of an opportunity index in Appendix B.

D.1.c. Transportation Assumptions

Appendix A.1 Section C - Estimates of Where an Oil Spill May Go discusses the transportation assumptions for the launch areas and their associated pipelines.

D.1.d. Results for the Chance of a Spill Occurring

Using the above spill rates, Table A.1-5 shows the chance of one or more spills occurring for the Proposal and alternatives. For the Proposal alternatives, we estimate 0.04-0.05 pipeline spills and 0.05-0.06 platform (and well) spills. The chance of one or more pipeline spills is 4-5%, and the chance of one or more platform spills is 5-6%. The chance of one or more spills total is 8-10 % for each sale.

D.2. Chance of a Spill Contacting

The chance of a spill contacting is taken from the oil-spill-trajectory model results summarized in Section C.4.a(1) and listed in Tables A2-1 through A2-54.

D.3. Results of the Oil-Spill-Risk Analysis: Combined Probabilities

Tables A2-55 through A2-72 show the annual combined probabilities for the Proposal and the alternatives. For the most part, the chance of one or more spills occurring and contacting resources and land segments is less than 0.5%. The relative risk from the Proposal and alternatives is low, because we do not expect oil spills to occur and contact resources or coastline. Because the combined probabilities are so low it is difficult to distinguish differences between the Proposal and alternatives based on combined probabilities.

E. Small Oil Spills

Small spills are spills that are less than 1,000 barrels. We analyze the effects of small spills in Section C.4.a.(1) We consider two types of small spills–crude oil and refined oil.

We use the Alaska North Slope record of small spills, because the spill rate is significantly less than the Gulf of Mexico OCS small spill rate. The OCS rate of crude and refined small spills is approximately 3,460 spills per billion barrels, and the North Slope rate is approximately 618 spills per billion barrels. We expect the same companies and regulators to participate offshore in the Beaufort Sea as those that are now operating on the onshore Alaska North Slope. We believe it is reasonable to assume that the rate in the Beaufort Sea will be similar to the rate on the Alaska North Slope.

The analysis of operational small oil spills uses historical oil-spill databases and simple statistical methods to derive general information about small crude and refined oil spills that occur on the Alaska North Slope. This information includes estimates of how often a spill occurs for every billion barrels of oil produced (oil-spill rates), the mean (average) number of oil spills, and the mean and median size of oil spills from facilities, pipelines, and flowlines combined. We then use this information to estimate the number, size, and distribution of operational small spills that may occur from Beaufort Sea Sales 186, 195, and 202. The analysis of operational small oil spills considers the entire production life of the Beaufort Sea sales and assumes the following:

- commercial quantities of hydrocarbons are present in the multiple-sale Program Area, and
- these hydrocarbons will be developed and produced at the estimated resource levels.

Uncertainties exist, such as

- the estimates required for the assumed resource levels, or
- the actual size of a crude- or refined-oil spill.

We use the history of crude and refined oil spills reported to the State of Alaska, Department of Environmental Conservation and the Joint Pipeline Office to determine crude- and refined-oil-spill rates and patterns from Alaska North Slope oil and gas exploration and development activities for spills greater than or equal to 1gallon and less than 1,000 barrels. Refined oil includes aviation fuel, diesel fuel, engine lube, fuel oil, gasoline, grease, hydraulic oil, transformer oil, and transmission oil. The Alaska North Slope oil-spill analysis includes onshore oil and gas exploration and development spills from the Point Thompson Unit, Badami Unit, Kuparuk River Unit, Milne Point Unit, Prudhoe Bay West Operating Area, Prudhoe Bay East Operating Area, and Duck Island Unit.

The Alaska North Slope oil-spill database of all spills greater than or equal to 1 gallon is from the State of Alaska, Department of Environmental Conservation. Oil-spill information is provided to the State of

Alaska, Department of Environmental Conservation by private industry according to the State of Alaska Regulations 18 AAC 75. The totals are based on initial spill reports and may not contain updated information. The State of Alaska, Department of Environmental Conservation database integrity is most reliable for the period 1989 and after due to increased scrutiny after the Exxon Valdez oil spill (Volt, 1997, pers. commun.). For this analysis, the database integrity cannot be validated thoroughly. However, we use this information, because it is the only information available to us about small spills. For this analysis, the State of Alaska, Department of Environmental Conservation database is spot-checked against spill records from ARCO Alaska, Inc. and British Petroleum, Inc. All spills greater than or equal to1 gallon are included in the data set. We use the time period January 1989-December 2000 in this analysis of small oil spills for the Beaufort Sea multiple-sales.

A simple analysis of operational small oil-spills is performed. Alaska North Slope oil-spill rates are estimated without regard to differentiating operation processes. The State of Alaska, Department of Environmental Conservation database base structure does not facilitate quantitative analysis of Alaska North Slope oil-spill rates separately for platforms, pipelines, or flowlines.

E.1. Results for Small Operational Crude Oil Spills

The analysis of Alaska North Slope crude oil spills is performed collectively for all facilities, pipelines, and flowlines. The pattern of crude oil spills on the Alaska North Slope is one of numerous small spills. Of the crude oil spills that occurred between 1989 and 2000, 31% were less than or equal to 2 gallons; 55% were less than or equal to 5 gallons. Ninety-eight percent of the crude oil spills were less than 25 barrels, and 99% were less than 60 barrels. The spill sizes in the database range from less than 1 gallon to 925 barrels. The average crude oil-spill size on the Alaska North Slope is 2.7 barrels, and the median spill size is 5 gallons. For purposes of analysis, this EIS assumes an average crude oil-spill size of 3 barrels.

Table A.1-6a shows the estimated crude oil-spill rate for the Alaska North Slope is 178 spills per billion barrels produced. Table A.1-6b shows the assumed number, size, and total volume of small spills for the proposal and alternative. Table A.1-6c shows the assumed size distribution of those spills for the Proposal and alternatives.

The causes of Alaska North Slope crude oil spills, in decreasing order of occurrence by frequency, are leaks, faulty valve/gauges, vent discharges, faulty connections, ruptured lines, seal failures, human error, and explosions. The cause of approximately 30% of the spills is unknown.

E.2. Results for Small Operational Refined Oil Spills

The typical refined products spilled are aviation fuel, diesel fuel, engine lube, fuel oil, gasoline, grease, hydraulic oil, transformer oil, and transmission oil. Diesel spills are 58% of refined oil spills by frequency and 83% by volume. Engine lube oil spills are 10% by frequency and 3% by volume. Hydraulic oil is 26% by frequency and 10% by volume. All other categories are less than 1% by frequency and volume. Refined oil spills occur in conjunction with oil exploration and production. The refined oil spills correlate to the volume of Alaska North Slope crude oil produced. As production of crude oil has declined, so has the number of refined oil spills. Table A.1-6d shows that from January 1989-December 2000, the spill rate for refined oil is 440 spills per billion barrels produced. Table A.1-6e shows the assumed refined oil spills during the lifetime of the Proposal and alternatives.

Key:
ID = identification (number).
3A = Fine- to Medium-grained Sand Beaches.
3C = Tundra Cliffs.
5= Mixed Sand and Gravel Beaches.
6A = Gravel Beaches.
7 = Exposed Tidal Flats.
8B = Sheltered, Solid Man-made Structures.
8E = Peat Shorelines.
9A= Sheltered Tidal Flats
10A = Salt- and Brackish- water Marshes.
10E = Inundated Low-lying Tundra.
U= Unranked.

LA16, LA17 & LA18	P7 to P13

Table A1-4
Launch Area and Pipeline Segment Exclusions by Sale Scenario for Production and Development

Sale 186/195	
Alternative I	LA1-LA6, LA11, LA13, LA14, LA16, LA18, P1, P2, P5, P6, P8, P11
Alternative III	LA1-LA6, LA11, LA13, LA14, LA16, LA18, P1, P2, P5, P6, P8, P11
Alternative IV	LA1-LA6, LA11, LA13, LA14, LA16, LA18, P1, P2, P5, P6, P8, P11
Alternative V	LA1-LA6, LA11, LA13, LA14, LA16, LA18, P1, P2, P5, P6, P8, P11
Alternative VI	LA1-LA6, LA11, LA13, LA14, LA16, LA18, P1, P2, P5, P6, P8, P11
Alternative III, IV, V and VI, are the same as Alternative I	

Note:
Where the majority (≥80%) of the spill points were removed from the spill area based on the scenario the spill area was excluded even if a small portion (<20%) of the spill area could be leased.

Sale 202	
Alternative I	LA8, LA10
Alternative III	LA8, LA10
Alternative IV	LA8, LA10
Alternative V	LA8, LA10
Alternative VI	LA8, LA10
Alternatives IV, V and VI, are the same as Alternative I.	

Table A1-5
Estimated Percent Chance of One or More Platform, Pipeline and Total Spills for Alternative I (Sales 186, 195 and 202) and Their Alternatives

Alternative		Percent Chance of One or More Platform Spills	Percent Chance of One or More Pipeline Spills	Percent Chance of One or More Spills Total
I	Alternative I	6	5	10
II	No Sale	0	0	0
III	Barrow Subsistence Whale Deferral	6	5	10
IV	Nuiqsut Subsistence Whale Deferral	6	4	10
V	Kaktovik Subsistence Whale Deferral	6	5	10
VI	Eastern Deferral	6	5	10

Table A1-6a
Small Spills Greater than or Equal to 1 Gallon and Less than 1,000 Barrels Table A1-6a Small Crude-Oil Spills: Estimated Spill Rates for the Alaska North Slope

Small Crude-Oil Spills ≤500 barrels, 1898-2000		
Total Volume of Spills	135,127 gallons	
—	3,217 barrels	
Total Number of Spills	1,178 spills	**Note:** Oil-spill databases are from the ADEC, Anchorage, Juneau, and Fairbanks. Alaska North Slope production data are derived from the TAPS throughput data from Alyeska Pipeline. **Source:** USDOI, MMS, Alaska OCS Region, 2002.
Average Spill Size	2.7 barrels	
Production (Crude Oil)	6.6 billion barrels	
Spill Rate	178 spills/billion barrels of crude oil produced	
Small Crude-Oil Spills > 500 barrels and <1,000, 1985-2000		
Total Volume of Spills	171,150 gallons	
—	4,075 barrels	
Total Number of Spills	6	**Note:** Oil-spill databases are from the ADEC, Anchorage, Juneau, and Fairbanks. BP Alaska Inc. and Arco. Alaska North Slope production data are derived from the TAPS throughput data from Alyeska Pipeline. **Source:** USDOI, MMS, Alaska OCS Region, 2002.
Average Spill Size	680 barrels	
Production (Crude Oil)	9.36 billion barrels	
Spill Rate	0.64 spills/billion barrels of crude oil produced

APPENDIX B

OIL AND GAS RESOURCE ESTIMATES

OIL AND GAS RESOURCE ESTIMATES

Geologic assessments of undiscovered oil and gas resources are used by the MMS to identify prospective areas for leasing and as a basis for analysis of future petroleum activities. We assume that the effects of petroleum development will be proportional to oil volumes produced. It is reasonable to assume that industry will only develop discoveries that are economically viable (or commercial). Most of the oil and gas resources in arctic offshore provinces are noncommercial for geologic reasons (pools are too small) and economic reasons (oil prices do not support development costs).

Resource-assessment models evaluate the geologic and engineering characteristics of hypothetical new fields and the transportation and marketing factors associated with their production. Computer models (*GRASP* and *PRESTO*) determine the economic viability of discoveries by simulating field discovery, development, and production activities and performing a discount cash-flow analysis of the cost and income streams. Simulated projects that have positive net present value have their resources added to the total economic volume available in the province. A detailed description of MMS assessment methodology is provided in Sherwood et al., 1998.

The process of estimating undiscovered oil and gas resources has many uncertainties. Although the size, number, and location of prospects (potential traps) can be identified using seismic surveys, actual oil and gas reservoirs cannot be confirmed without drilling. In a frontier area with limited seismic data coverage, most of the modeled undiscovered resources could occur in pools that are not identified. The reservoirs, source rocks, and seals associated with the prospects are inferred from nearby wells (well logs) or by comparisons to known pools (analogs). Development cost estimates also are uncertain, because relevant projects may not have been completed under the equivalent environmental conditions.

Because of the many geologic, engineering, and economic uncertainties, resource estimates typically are presented as a range of values associated with probability levels. We report a “low case” at a 95% probability level (a 19-in-20 chance of occurrence), an “expected case” (mean or average) of the range, and a “high case” at 5% probability (1-in-20 change of occurrence). Larger volumes are associated with lower probabilities. Economic uncertainties are handled by using a range of market prices (a price of $18 and $30 per barrel). Typically, higher prices support greater levels of activity and more resources discovered and developed.

New resource assessments often differ from older assessments, because geologic concepts evolve with new data. Despite decreasing sophistication of technology, many discoveries are made inadvertently while drilling for different reservoir targets. No one can predict when and where commercial-sized fields will be found. The prospect inventory is likely to be different for each company. Increasing the area open to leasing and exploration will increase the likelihood of future discoveries. In a frontier area, area equates to opportunity.

B.1 Geologic Play Concepts

Undiscovered petroleum resources are modeled using a geologic play analysis. Each geologic play is defined by unique characteristics such as reservoirs, trap types, and similar geologic histories. Plays typically contain many prospects (untested but potential traps for oil/gas pools); some are mapped and some are unidentified. Proven plays contain oil and gas discoveries, and future exploration success rates generally are higher in the play, because all of the key elements are known to be present. Unproven plays have not been tested by drilling or lack discoveries in exploration tests. The majority of petroleum resources often is contained in unidentified prospects that either have not been mapped (lack of seismic data) or cannot be mapped using available data (require 3-dimensional seismic and well control). Consequently, estimating the oil and gas resource potential is speculative, even with the aid of complex computer models.

The regional geology and assessment methodology for the Beaufort province is discussed in detail by Sherwood et al., 1998, and the results presented here are an update of this assessment effort. Minor adjustments in play boundaries between the adjacent Beaufort and Chukchi planning areas and minor corrections to previous modeling inputs resulted in similar conclusions for the current (2002-2007) leasing-program area. The brief play descriptions that follow essentially are unchanged from the earlier 1995 assessment, because there has been very little exploration activity on the Beaufort Shelf since the 1995 assessment. The regional geologic history and stratigraphy are discussed in Section III.A.

The **Undeformed Pre-Mississippian Basement Play** consists of carbonate or sandstone reservoirs of the Franklinian sequence (Figure III.A.3). This play is unproven, because no OCS wells have reported pooled oil/gas. However, encouraging well tests were made on Flaxman Island.

The **Endicott Play** consists of sandstone reservoirs of the Mississippian Endicott Group (Figure III.A.3). This play is proven, because oil and gas fields were discovered at Endicott/Duck Island and Tern/Liberty, although two OCS wells were unsuccessful tests in this play.

The **Lisburne Play** consists of limestone and dolomite reservoirs of the Mississippian to Pennsylvanian age Lisburne Group (Figure III.A.3). This play is proven, because there is production in the Lisburne field onshore. Six OCS wells have tested the play without a commercial success.

The **Upper Ellesmerian Play** consists of Triassic and Permo-Triassic sandstone reservoirs of the Sag River Formation and Sadlerochit Group (Figure III.A.3). This play is considered proven, because most of the North Slope reserves are contained in this play, most notably the Prudhoe Bay field. The play has been tested by 13 OCS wells, resulting in the discovery of 2 offshore oil and gas fields (Northstar and Sandpiper).

The **Rift Play** consists of sandstone reservoirs of Jurassic to early Cretaceous age (Figure III.A.3). The play is proven, because there are many fields producing from these reservoirs on the North Slope (including the South Barrow, East Barrow, and Walakpa gas fields in the National Petroleum Reserve-Alaska, and Kuparuk River, Milne Point, Point McIntyre, Alpine, Niakuk, and other satellites) in addition to the undeveloped Point Thomson gas-condensate field. The play has been tested at several locations on the Beaufort shelf, raging from Aurora (east of Barter Island) to Cabot (near Barrow), without a commercial success.

The **Brookian Unstructured Western Topset Play** is an unproven play located on the inner to middle shelf in the western part of the Beaufort Sea. The play consists of deltaic sandstone reservoirs (Nanushuk Group) in early Cretaceous strata of the Brookian sequence (Figure III.A.3). Although discoveries have not been made offshore, several oil shows have been reported in the northern National Petroleum Reserve-Alaska (Simpson and Fish Creek).

The **Brookian Faulted Western Topset Play** is an unproven play located on the middle to outer shelf in the western Beaufort Sea. The play consists of Cretaceous deltaic sandstone reservoirs assigned to the Nanushuk and Colville Group (Figure III.A.3). No prospects have been drilled in this play.

The **Brookian Unstructured Western Turbidite Play** is a proven play located on the inner Beaufort shelf west of the Colville River. It includes deepwater strata of Cretaceous age) Torok Formation and Colville Group) containing turbidite sandstone reservoirs (Figure III.A.3). Two onshore fields (Tarn and Meltwater) are producing oil from equivalent reservoirs. This play has been penetrated by numerous OCS wells without encountering a commercial pool. The Phoenix well tested heavy oil from Torok turbidite sands, and oil shows were reported in the Mukluk well.

The **Brookian Faulted Western Turbidite Play** is an unproven play located on the middle to outer shelf in the western Beaufort Sea. The play consists of deepwater strata of early Cretaceous (Torok Formation) to late Cretaceous (Colville Group) age assigned to the Brookian sequence (Figure III.A.3). Potential reservoirs include turbidite sands in submarine fan environments. No prospects have been tested in the play.

The **Brookian Unstructured Eastern Topset Play** is a proven play located on the inner to middle shelf in the central part of the Beaufort Sea. The play consists of late Cretaceous to Tertiary age deltaic sandstone reservoirs assigned to the Brookian sequence (Figure III.A.3). Oil was discovered in the OCS at Hammerhead and Kuvlum and is being produced onshore from reservoirs in the West Sak (Kuparuk River Unit) and Schader Bluff (Milne Point Unit). In Harrison Bay, the Phoenix well tested oil in Colville Group strata. The results of the Warthog well and Stinson nearshore wells remain confidential, because their bottomhole location was on State submerged lands.

The **Brookian Faulted Eastern Topset Play** is a proven play located on the middle to outer Beaufort shelf in the central part of the Beaufort Sea. The play consists of Cretaceous and Tertiary deltaic sandstone reservoirs assigned to the Brookian sequence (Figure III.A.3). One OCS well (Galahad) recovered gas and condensate; however, the well was not flow tested or certified as capable of producing in paying quantities. We are confident that oil and gas are pooled in the Galahad prospect, but current economics do not support very high appraisal and development costs.

The **Brookian Unstructured Eastern Turbidite Play** is a proven play on the inner to middle Beaufort shelf. It includes Late Cretaceous and Tertiary turbidite reservoirs localized in submarine fan complexes. Stratigraphic traps predominate and prospects are difficult to map without 3-dimensional seismic surveys. One nearshore OCS well (Beechy Point No. 2) flowed oil and gas out of a thin turbidite sand. Onshore, this play has produced oil in the Badami field.

The **Brookian Faulted Eastern Turbidite Play** is an unproven play on the middle to outer Beaufort shelf. It includes the late Cretaceous and Tertiary turbidite reservoirs assigned to the Brookian sequence (Figure III.A.3). Numerous prospects in the play are formed by faults related to the Hinge Line (Figure III.A.4). Stratigraphic traps probably also are present but are difficult to map using the available 2-dimensional seismic data. No wells have tested the play.

The **Brookian Foldbelt Play** is a proven play in the eastern Beaufort shelf. Potential reservoirs are primarily Tertiary strata assigned to the Brookian sequence (Figure III.A.3). The structural character of prospects is complex, because it is influenced by intersecting tectonic trends of the Brooks Range orogenic belt and Hinge Line fault system. Several OCS wells have tested this play with mixed results. Shows were reported from the Belcher well, although reservoir quality typically was poor in the Corona, Aurora, and Belcher wells. The play area extends (geologically) into Canadian waters, where a small oil pool was discovered at Adlartok. Other Canadian Beaufort wells contain good quality reservoir rocks (Natsek).

B.2 Assessment Results

The resource potential of the Beaufort shelf province was analyzed by computer models in spring 2001. Two sets of petroleum-resource estimates were generated. The updated assessment for the Beaufort Sea Planning Area reports a mean conventionally recoverable volume of 6.94 billion barrels of oil and 32.07 trillion cubic feet of gas. This estimate includes available resources (unleased and undiscovered) recoverable using current technology without regard to their economic viability.

Because most of the resource endowment occurs in pools too small or costly to develop, the economically recoverable resource estimates are lower. For the Beaufort Sea Planning Area, the mean economically recoverable resource estimate is 1.78 billion barrels of oil at $18.00 per barrel; and 3.24 billion barrels of oil is recoverable at $30.00 per barrel. The oil volumes at other probability levels are listed in Table B-1.

Resource estimates for the Beaufort Sea Planning Area are somewhat lower, because the area is smaller and opportunities for commercial discoveries are correspondingly reduced. No gas resources on the Beaufort OCS are shown as economically recoverable, because there is no gas-transportation system from arctic Alaska to outside markets.

The Beaufort Sea Planning Area contains petroleum resources in 14 geologic plays, 9 of which have been proven to contain oil or gas pools. Exploration drilling in the past has covered all parts of the Beaufort shelf out to a maximum water depth of about 50 meters (Belcher, 167 feet; Galahad, 166 feet). At $18.00 per barrel, three plays contain 95% of the total economically recoverable resources modeled in the planning area. Relative contributions are from the Rift play (38%), The Upper Ellesmerian play (37%), and the Brookian foldbelt play (20%). These areas covered by these three plays are shown in Figures B-1 and B-2. Of the three major plays, only the Brookian foldbelt play is affected by removing a large portion of the eastern Beaufort Sea Planning Area from the current program area.

At a higher price of $30.00 per barrel, the results are much the same. However, another play (Brookian unstructured eastern topset play) joins the previous plays to comprise 97% of the total available economic resources. Relative contributions are from the Rift play (39%), the Upper Ellesmerian play (29%), the

Brookian foldbelt play (20%), and the Brookian Unstructured Eastern Topset play (9%). The areas covered by these four plays are shown in Figures B-3 and B-4.

Industry activities in the Beaufort Sea generally support these conclusions. Exploration efforts (leasing, marine seismic surveys, and drilling) have focused on the nearshore of the central Beaufort. Most of the geologic plays present in this "core area" are proven by discoveries in the OCS or commercial production in adjacent coastal areas. Industry has actively leased and drilled Ellesmerian prospects, because they were expected to contain thick, highly productive reservoirs similar to the Prudhoe Bay field. Rift sequence prospects also have been of high industry interest because of the prolific nearshore fields, such as the Point McIntyre field. Prospects in the Brookian sequence generally have been overlooked in favor of more easily mapped prospects. However, with new exploration technologies (3-dimensional seismic surveys), Brookian stratigraphic prospects represent new exploration opportunities throughout the program area.

Table B-1
Summary of Resource Assessment for the Beaufort Sea Planning Area

Conventionally Recoverable	95% Probability	Mean (average)	5% Probability
Planning Area*	3.56	6.94	11.84
Program Area*			
$18.00 per barrel	**95% Probability**	**Mean (average)**	**5% Probability**
Planning Area*	0.00	1.78	6.64
Program Area*		1.68	
$30.00 per barrel	**95% Probability**	**Mean (average)**	**5% Probability**

MMS letter dated January 7, 2002 sending listed species for Proposed Beaufort Sea Multiple-Sale Oil and Gas Lease Sales to NMFS.

NMFS letter response dated February 11, 2002 indicating that they recently revised the Arctic Regional Biological Opinion in May 2001.

USFWS memorandum dated October 22, 2002 forwarding the Biological Opinion for Sale 186.

MMS memorandum dated May 9, 2002 requesting formal consultation with USFWS under the ESA, and forwarding the Draft EIS for the Proposed Beaufort Sea Multiple-Sale Oil and Gas Lease Sales.

MMS letter dated May 9, 2002 requesting formal consultation with NMFS under the ESA, forwarding the Draft EIS for the Proposed Beaufort Sea Multiple-Sale Oil and Gas Leasing Sales, and inquiring as to the status of May 2001 NMFS Biological Opinion in light of the Proposed Beaufort Sea Multiple-Sale Oil and Gas Lease Sales.

NMFS letter response dated July 23, 2002 to MMS saying that the previous May 2001 Biological Opinion was relevant to the Proposed Beaufort Sea Multiple-Sale Oil and Gas Lease Sales. This consultation is applicable to Sale 186.

United States Department of the Interior

MINERALS MANAGEMENT SERVICE
Alaska Outer Continental Shelf Region
949 East 36th Avenue, Suite 300
Anchorage, Alaska 99508-4363

JAN - 7 2002

Memorandum

To: Regional Director, U.S. Fish and Wildlife Service

From: Regional Director

Subject: Endangered Species - Proposed Beaufort Sea Multi-Sale Oil and Gas Lease Sale

The Minerals Management Service has initiated the planning process for leasing and exploration associated with the proposed Outer Continental Shelf (OCS) Beaufort Sea Multi-Sale Oil and Gas Lease Sale plan for the Beaufort Sea. The multi-sale plan provides for three sales in the Beaufort Sea Planning Area, Sale 186 in 2003, Sale 195 in 2005, and Sale 202 in 2007, as described in the Draft OCS Oil and Gas Leasing Program: 2002-2007. The planning area will be identical to the program area adopted in the 1997-2002 OCS Oil and Gas Leasing Program (see enclosure).

In accordance with the Endangered Species Act section 7 regulations governing interagency cooperation, we are providing a notification of the listed and proposed species and critical habitat that will be included in our biological evaluation.

In our biological evaluation, we will review the following listed species that may be present in the proposed sale area.

Common Name	Scientific Name	Status
Spectacled eider	*Somateria fischeri*	threatened
Steller's eider	*Polysticta stelleri*	threatened

It is our understanding there is no designated or proposed critical habitat for any listed or proposed species in OCS regions potentially affected by activities associated with the Beaufort Sea Multi-Sale plan.

In previous consultations with the Fish and Wildlife Service (FWS) we also consulted on listed species and critical habitat along the transportation corridor from Valdez to ports along the Pacific coast and to the Far East. In the most recent section 7 consultation on the Liberty Development and Production Project, the FWS elected to address the effects of oil-tankering on listed species/critical habitat through a separate consultation with the U.S. Coast Guard in recognition of the Coast Guard's statutory authority relative to tankering activities. In addition, the National Marine Fisheries Service (NMFS) determined they would not be able to meaningfully measure, detect, or evaluate the effects associated with the transportation corridor.

NMFS therefore considered these effects as discountable and did not include them in the biological opinion for the proposed action. We understand that NMFS also may consider addressing the effects of oil-tankering on listed species/critical habitat through a separate consultation with the U.S. Coast Guard. Accordingly, we do not plan to consult on listed species and critical habitat along the transportation corridor from Valdez to ports along the Pacific coast and to the Far East.

Please review our list and notify us of your concurrence or necessary revisions and of any new information concerning these species or other species under FWS jurisdiction in relation to the proposed project. Also please advise us on the necessity to consult on the transportation corridor based on the discussion in the previous paragraph. To facilitate the review, we have provided a copy of this letter to your Northern Alaska Ecological Services Field Office. Upon receipt of your reply, we will begin preparation of the biological evaluation reviewing potential effects of the proposed action.

We look forward to working with you and your staff in protecting and conserving endangered and threatened species. If you have any questions concerning this proposed action, please contact Joel Hubbard at (907) 271-6670 or Frank Wendling at (907) 271-6510.

IN REPLY REFER TO:

AFES

FEB 11 2002

Memorandum

To: Regional Director - Minerals Management Service

From: Regional Director - Region 7

Subject: Endangered Species - Proposed Beaufort Sea Multi-Sale Oil and Gas Lease Sale

This memorandum constitutes the U.S. Fish and Wildlife Service's response to your memorandum dated January 7, 2002, in which you requested concurrence on two issues relating to consultation of the effects of a proposed Outer Continental Shelf Multi-Sale Oil and Gas Lease Sale plan for the Beaufort Sea on threatened and endangered wildlife.

First, you asked us to review your list of threatened and endangered species that may be present in the proposed sale area. We concur that Spectacled Eiders (Somateria fischeri) and Steller's Eiders (Polysticta stelleri) may occur in the proposed sale area. We also agree that there is no designated or proposed critical habitat for listed species that would likely be affected by the proposed lease sale.

Second, you asked us to comment on the necessity to include an evaluation of the impacts of transporting oil from Valdez to ports along the Pacific coast and the Far East in your biological evaluation and the ensuing consultation. We continue to believe that it is preferable to address the effects of oil-tankering on listed species in a separate consultation with the U.S. Coast Guard, rather than consulting on the effects piecemeal during multiple consultations on lease sales and development projects. There is no need, therefore, to include an evaluation of the effects of oil-tankering in your biological evaluation or the ensuing consultation on the proposed lease sale.

Thank you for your interest in protecting threatened and endangered species. If you have any questions about our response, please contact Patrick Sousa, Field Supervisor, Northern Alaska Ecological Services Field Office, at (907) 456-0327 or Ted Swem, Endangered Species biologist, Northern Alaska Ecological Services Field Office, at (907) 456-0441.

Anchorage, Alaska 99508-4363

JAN - 7 2002

Mr. James Balsiger
Regional Administrator, Alaska Region
National Marine Fisheries Service
P.O. Box 21668
Juneau, Alaska 99802-1668

Dear Mr. Balsiger:

The Minerals Management Service has initiated the planning process for leasing and exploration associated with the proposed Outer Continental Shelf (OCS) Beaufort Sea Multi-Sale Oil and Gas Lease Sale plan for the Beaufort Sea. The multi-sale plan provides for three sales in the Beaufort Sea Planning Area, Sale 186 in 2003, Sale 195 in 2005, and Sale 202 in 2007, as described in the Draft OCS Oil and Gas Leasing Program: 2002-2007. The planning area will be identical to the program area adopted in the 1997-2002 OCS Oil and Gas Leasing Program (see enclosure).

In accordance with the Endangered Species Act section 7 regulations governing interagency cooperation, we are providing a notification of the listed and proposed species and critical habitat that will be included in our biological evaluation.

In our biological evaluation, we will review the following listed species that may be present in the proposed sale area.

Common Name	Scientific Name	Status
Bowhead whale	*Balaena mysticetus*	endangered

It is our understanding there is no proposed or designated critical habitat for any listed or proposed species in OCS regions potentially affected by activities associated with the Beaufort Sea Multi-Sale plan.

In previous consultations with the National Marine Fisheries Service (NMFS) we also consulted on listed species and critical habitat along the transportation corridor from Valdez to ports along the Pacific coast and to the Far East. In the most recent section 7 consultation on the Liberty Development and Production Project, NMFS determined they would not be able to meaningfully measure, detect, or evaluate the effects associated with the transportation corridor. NMFS therefore considered these effects as discountable and did not include them in the biological opinion for the proposed action. In addition, we understand that the Fish and Wildlife Service and NMFS have elected to address the effects of oil-tankering on listed species/critical habitat through a separate consultation with the U.S. Coast Guard in recognition of the Coast Guard's statutory authority relative to tankering activities. Accordingly, we do not plan to consult on listed species and critical habitat along the transportation corridor from Valdez to ports along the Pacific coast and to the Far East.

Please notify us of your concurrence or necessary revisions and of any new information concerning this species or other species under your agency's jurisdiction in relation to the proposed project. Also please advise us on the necessity to consult on the transportation corridor based on the discussion in the previous paragraph. To facilitate the review, we have provided a copy of this letter to your Anchorage field office. Upon receipt of your reply, we will begin preparation of the biological evaluation reviewing potential effects of the proposed action.

We look forward to working with you and your staff in protecting and conserving endangered and threatened species. If you have any questions concerning this proposed action, please contact Frank Wendling at (907) 271-6510 or Joel Hubbard at (907) 271-6670.

Sincerely,

John T. Goll
Regional Director

February 11, 2002

RECEIVED
JAN ? 2002
REGIONAL DIRECTOR, ALASKA OCS
Minerals Management Service
ANCHORAGE, ALASKA

John T. Goll
Director,
Alaska Outer Continental Shelf Region
Minerals Management Service
949 East 36th Avenue, Suite 300
Anchorage, Alaska 99508-4363

Dear Mr. Goll:

Thank you for your letter regarding threatened and endangered species which might be affected by the proposed Beaufort Sea Multi-Sale Oil and Gas Lease Sale. We agree with your determination to confine the biological evaluation to one listed species; the bowhead whale. Separate consultations are underway or will be initiated regarding the effects of the Trans-Alaska Pipeline System and the marine transport of oil from the terminal at Valdez. We are therefore in agreement with the position of Minerals Management Service not to consult on listed species and critical habitat along the pipeline or out of Valdez.

The Arctic Regional Biological Opinion (ARBO) was revised in May 2001, and we expect that document will continue to represent the most current assessment of the effects of leasing actions in the Beaufort Sea on the bowhead whale. We will confirm the applicability of the ARBO after reviewing the Biological Evaluation for this multi-sale.

We appreciate this opportunity for comment. Please direct any questions to Brad Smith in our Anchorage office at (907) 271-5006.

Sincerely,

James W. Balsiger
Administrator, Alaska Region

OCT 22 2002

Memorandum

To: Regional Director - Minerals Management Service

From: Acting Regional Director - Region 7

Subject: Section 7 Consultation for Proposed Beaufort Sea Natural Gas and Oil Lease Sale 186 - Final Biological Opinion

This memorandum transmits the U.S. Fish and Wildlife Service's final no jeopardy biological opinion based on our review of the Minerals Management Service's proposed Natural Gas and Oil Lease Sale 186 and associated exploration activities in the Beaufort Sea Planning Area in accordance with Section 7 of the Endangered Species Act (Act) of 1973, as amended (16 U.S.C. 1531 et seq.).

Over the last several weeks our staff worked closely together in reviewing and revising the document. We appreciated the open, and constructive dialogue that led to the finalization of the biological opinion. We look forward to working collaboratively with the Minerals Management Service staff in implementing the terms and conditions of the biological opinion. If your staff have any questions regarding the final biological opinion, please have them contact Steve Lewis, Project Leader, Fairbanks Fish and Wildlife Field Office, at (907) 456-0272, or Jonathan Priday, Endangered Species Biologist, FFWFO, at (907) 456-0499.

Attachment

Doing visual inspection for mercury/worker safety? What are your analytical costs for mercury (see low)?

While a visual inspection will be used to direct soil sampling, potential mercury hazards will be investigated by sampling up to 50 locations in and around Peavy. Again there was a miscommunication regarding this proposal and a revised budget is attached.. Our current best estimate is $6,550 for PACF analytical: 50 soil/sediment samples for cold vapor mercury analysis ($64 each) with sample preparation costs of $67 per sample. RTI contact costs were used to prepare this estimate. Actual costs may be lower, depending on which lab performs the analysis.

Biological Opinion
for Minerals Management Service's
Proposed Beaufort Sea Natural Gas and Oil Lease Sale 186

Introduction

This documents transmits the U.S. Fish and Wildlife Service's (Service) final biological opinion based on our review of the Minerals Management Service's (MMS) proposed Natural Gas and Oil Lease Sale 186 and associated exploration activities in the Beaufort Sea Planning Area in accordance with Section 7 of the Endangered Species Act (Act) of 1973, as amended (16 U.S.C. 1531 et seq.). The MMS's May 9, 2002, request for formal consultation was received on May 29, 2002. The MMS requested programmatic Section 7 consultation for proposed Beaufort Sea lease sales from 2003 through 2007 identified as Lease Sales 186, 195, and 202. The May 2002 Draft Alaska Outer Continental Shelf (OCS) Environmental Impact Statement (EIS) states that it is the sole National Environmental Policy Act (NEPA) analysis for Lease Sale 186 and that MMS will prepare an Environmental Assessment (EA) or supplemental EIS for Sales 195 and 202. Based upon the information contained in any future EA or supplemental EIS, the MMS will reinitiate programmatic consultation on Lease Sales 195 and/or 202 at later dates if new information comes to light that would trigger the need for reinitiation.

The MMS requested that the following biological opinion supercede previous consultations on all prior and existing lease sale activity in the Beaufort Sea. The Service and MMS previously consulted on OCS Lease Sales 124, 144, and 170, all of which overlap with portions of the area covered in Lease Sale 186. Thus far, leases on all or parts of 60 blocks have been sold in previous actions resulting in one exploration project, McCovey, and two development/production projects, Liberty and the Northstar project. Consultations for the McCovey, Liberty, and Northstar projects have been completed. However, since the McCovey exploration project falls within the current proposed action, the final biological opinion for Lease Sale186 will supercede the prior consultations covering McCovey. This biological opinion does not affect the consultations completed on the Northstar and Liberty projects.

For actions such as OCS oil and gas lease sales that are completed in incremental steps, the Service issues biological opinions on each step being considered. The following "incremental step" consultation is appropriate for long-term, multi-staged activities such as Lease Sale 186, for which agency actions occur in discrete steps. Although this is an "incremental step" consultation on leasing and exploration, information was also provided by MMS on potential development and production scenarios so that the Service could evaluate the likelihood of the entire action proceeding without violating Section 7(a)(2) of the Act.

In the first step of an incremental consultation, the Service must evaluate not only the proposed action, but also the potential entire action in order to determine the likelihood of the entire action violating Section 7(a)(2) of the Act. In this case, leasing and exploration are the proposed actions. Subsequent actions such as development and production are actions that may occur at a later date and will require separate consultations. Based on the information provided on the proposed and potential activities, and the information currently available on listed and proposed species and designated and proposed critical habitat, the Service has determined that it is unlikely that the entire action, including development and production, will violate Section 7(a)(2) of the Act.

This final biological opinion is based on information provided in the May 2002 Draft Alaska OCS Environmental Impact Statement and other sources of supplied information to evaluate the effects of the proposed leasing and exploration actions. The following document represents the Service's biological opinion on the effects of that action on the threatened spectacled eider (*Somateria fischeri*) and Steller's eider (*Polysticta stelleri*), in accordance with Section 7 of the Act.

A chronology of the consultation actions regarding Lease Sale 186 is provided in Attachment 1. A complete administrative record of this consultation is on file at the Fairbanks Fish and Wildlife Field Office, 101 12th Ave., Box 19, Fairbanks, Alaska 99701.

Description of the Proposed Action

The activities considered in this consultation are oil and gas lease sales and subsequent exploratory drilling, testing, and surveying. Separate consultations for development and production activities will be conducted if oil is discovered and development plans are proposed. Lease Sale 186 is tentatively scheduled for September 2003. If held, Lease Sale 186 would be the eighth Federal offshore sale in the Beaufort Sea Planning Area. The proposal would offer for lease 1,877 blocks encompassing about 3.9 million hectares (9.7 million acres). The blocks that comprise the proposed action are approximately 3 to 25 nautical miles offshore in water depths that range from approximately <1 to 1,500 meters (2 to 4,900 feet).

Six exploration and 6 delineation wells are proposed to be drilled during the period 2004 through 2010. The project description indicates that a maximum of two drilling rigs would be operable in any one exploratory year, assuming one exploration rig per platform. According to MMS's estimates within the Lease Sale 186 EIS, it is likely that one exploration well will be drilled per year for 6 consecutive years starting in 2004.

Based on geologic studies, the MMS indicates that each exploratory or delineation well would require 425 short tons of drilling muds (dry weight) and produce approximately 525 short tons of dry rock cuttings. The MMS estimates 935-1,040 short tons (dry weight) of drilling muds and 5,775-6,300 short tons (dry weight) of bore cuttings would need to be disposed for the exploration and delineation activities for Lease Sale 186.

If the first commercial discovery is made in 2005, 2 years after the sale date in 2003, production from Lease Sale 186 would begin by 2010. Between 2009 and 2014, three production facilities are likely to be brought online. The MMS estimates ~70 percent of production facilities would be located between the Canning River on the east and Colville River on the west in water depths less than 10 meters (Near Zone), ~30 percent would be located between Barter Island in the east to Cape Halkett in the west in water depths between 10 and 30 meters (Midrange Zone), and 0 percent would be located in the remainder of the program area extending from Barrow on the west to the Canadian boarder on the east (Far Zone). Spectacled eiders, especially females and broods, utilize the nearshore area of all three of these zones, especially areas offshore from the Colville Delta, Harrison Bay and Smith Bay (TERA 2002, review). Aerial surveys in the central Beaufort area done in 1999 and 2000 estimated that 166-371 spectacled eiders could have utilized the area that includes the Near and western Mid Zones (Stehn and Platte 2000). Steller's eiders are rarely found in the Far Zone and even less common farther east into the Mid- and Near Zones. Drilling production and injection wells are projected to begin in 2009 and conclude in 2017, with a total of 102 wells drilled. Oil production from Lease Sale 186 would end by 2033. Offshore pipeline construction is slated to begin in 2009 and finish in 2015, with 40 miles of new offshore pipeline installed. The offshore pipeline would likely connect to existing onshore pipelines.

Ice roads are assumed to be the principal transportation mode for routine supplies and materials to be transported to ice islands and/or nearshore gravel islands. For drilling platforms farther offshore in the broken-ice zone, material and supplies would be transported by support/supply boats (with icebreaking capacity, if necessary) during the open-water season and by helicopter at other times. For both types of drilling structures, most personnel would be transported by helicopters. The number of helicopter trips flown in support of exploration- and delineation-well drilling is assumed to range from about 90-270 each year, depending on the number of wells (1-3) that are drilled. For each drilling operation, there would be 1 flight per day of drilling. The time required to drill and test a well is about 90 days.

In the formulation of this biological opinion, the Service considered activities that would be interrelated and interdependent to the proposed action as well as accidental events that may occur as a result of the proposed action. Interrelated actions are those actions that are part of a larger action and depend on the larger action for their jurisdiction. Interdependent actions are those actions that have no independent utility apart from the action being considered in the biological opinion. Interrelated and interdependent activities that may occur in conjunction with the proposed action include construction of onshore support facilities, construction of onshore and offshore pipelines, and accidental oil spills originating from platforms, pipelines, and supply vessels.

STATUS OF THE LISTED SPECIES

Spectacled eider

The spectacled eider was listed as a threatened species under the Act in May 1993. Currently, primary nesting grounds are the Yukon-Kuskokwim Delta, the North Slope (Cape Simpson to the Sagavanirktok River) of Alaska, and in the Chaun Gulf and the Kolyma, Indigirka, and Yana river deltas of Arctic Russia. Post-breeding flocks of staging and molting spectacled eiders have been observed in Mechigmenan Bay (on the eastern coast of Russia's Chukotsk Peninsula), Alaska's Ledyard Bay (southwest of Point Lay), Peard Bay, Norton Sound, and 80 km south of Saint Lawrence Island. An estimated 7,370 spectacled eiders occupied the Arctic Coastal Plain of Alaska in June 2001 (Larned et al. 2001a), about 2 percent of the estimated 375,000 world population (Larned and Tiplady 1999).

From late December to early April, the only known wintering area of spectacled eiders is among leads in the pack ice southwest of St. Lawrence Island in the Bering Sea (Petersen et al. 1999). Leads in ocean ice are important pathways for marine bird and mammal species migrating along the Beaufort Sea coast in Alaska and Canada. All species of eiders use this lead system as well, flying at altitudes that are usually less than 30 meters (Johnson and Richardson 1982). Very little is known about migratory routes east of Barrow, but the definitive lead system transforms into numerous branches varying in location and extent from year-to-year. Because few spectacled eiders are observed in marine areas along the Beaufort coast in spring, a majority may migrate to the nesting areas overland from the Chukchi Sea (TERA 2002, review). Migration of eiders (the majority of which are king and common eiders) along Alaska's northern coast has been described in several studies (Thompson and Person 1963, Johnson 1971, Woodby and Divoky 1982). Spectacled eiders are observed in mixed flocks of king, common, and sometimes Steller's eiders, but the percentage of both spectacled and Steller's eiders is quite small.

Spectacled eiders arrive on North Slope breeding grounds paired, often in small flocks, in late May to early June. Spectacled eider nests are widely separated, nesting mainly from the Sagavanirktok River to the Chukchi Sea, and only sparsely to the east (Larned et al. 2001a). The highest densities determined from Service aerial surveys for eiders in 1998-2001 on the Arctic Coastal Plain east to the Arctic National Wildlife Refuge were found south of Barrow, with smaller areas east of Teshekpuk Lake, on the Colville River Delta, and near western Simpson Lagoon. Overall density was determined as 0.24 birds per square kilometer in 2001 (Larned et al. 2001a).

Male spectacled eiders begin to depart breeding areas during incubation, which coincides with late June on the North Slope. On the North Slope, the number of pairs peaks in mid-June and the number of males declines 4-5 days later (Smith et al. 1994, Anderson and Cooper 1994, Anderson et al. 1995). Following their late June departure from the nesting areas, males apparently make little use of the Beaufort before migrating to the Chukchi Sea.

During late June the Beaufort Sea has little open water, hence males present at breeding grounds east of Barrow normally do not use marine habitats and fly directly overland (most heading to a molting/staging area in Ledyard Bay) (TERA 2002, review). Later in the season (late June through September), when females depart the North Slope, much more of the nearshore zone is ice free. Open water in marine habitat allows for extensive use of the western Beaufort Sea. Radio telemetry studies have shown that most female spectacled eiders that migrate west toward Barrow use the nearshore zone of the Beaufort Sea as they transit to their molting/staging areas. The 13 female spectacled eiders tracked by Troy et al. (2002, review) primarily used the western Beaufort (71 percent of all bird-days) while areas near Stockton Island were also extensively used (17 percent of all bird-days). The females remained in the Beaufort Sea nearshore zone for an average of about 2 weeks (range 6-30 days).

Predators of spectacled eider eggs include gulls, jaegers, and foxes. In Arctic Russia, apparent nest success has been calculated to be as low as <2 percent in 1994 and 27 percent in 1995; foxes, gulls, and jaegers are suspected to have depredated most of the nests (Pearce et al. 1998). On Kigigak Island in the Yukon-Kuskokwim Delta, nest success ranged from 20-95 percent in 1991-1995 (Harwood and Moran 1993, Moran and Harwood 1994, Moran 1995, Moran 1996). Nest success may have been higher in 1992 than in other years of observation, because foxes were eliminated from the Island prior to the nesting season that year. Nest success in 1991 and 1993-1995 in the Kuparuk and Prudhoe Bay oil fields on the North Slope ranged from 25-40 percent (Warnock and Troy 1992, Anderson et al. 1998).

Spectacled eider incubation lasts 20-25 days (Dau 1974, Kondratev and Zadorina 1992, Harwood and Moran 1993, Moran and Harwood 1994, Moran 1995). Hatching on the North Slope occurs from mid- to late July (Warnock and Troy 1992). Fledging occurs approximately 50 days after hatching. At this time, females with broods move directly from freshwater to marine habitats (Dau 1974, Kistchinski and Flint 1974).

On the nesting grounds, spectacled eiders feed by dabbling in shallow freshwater or brackish ponds, or on flooded tundra (Dau 1974, Kistchinski and Flint 1974). Food items include molluscs, insect larvae such as craneflies, trichopterans, and chironomids; small, freshwater crustaceans, and plants or seeds (Cottam 1939, Dau 1974, Kistchinski and Flint 1974, Kondratev and Zadorina 1992). Spectacled eiders in the marine environment feed predominately on clams and small amounts of snails, amphipods, and other bivalves. In March-April 1999 and 2001, studies within the spectacled eider wintering areas showed that the esophagi of collected eiders contained only clams, almost entirely *Nuculana radiata* with no trace of the once-dominant and preferred *Macoma calcarea* (Lovvorn 2002). Changes in the density of *Macoma calcarea* in the Bering Sea are coincident with an oceanic regime shift to warmer conditions in 1976-77 (Lovvorn et al. 2002 review). Exceptional climate change in the arctic and subarctic, and associated changes in marine communities and ice dynamics in spring, may have had important impacts on spectacled eiders whose declines of ~90 percent are largely unexplained.

timed in mid-June, indicates a smaller population, averaging about 200 birds from 1992-2001 (Larned et al. 2001b). These surveys likely underestimate actual population size, however, because an unknown proportion of birds are missed when counting from aircraft, and no species-specific correction factor has been developed and applied. Nonetheless, these observations indicate that hundreds or low thousands of Steller's eiders occur on the North Slope. These surveys do not demonstrate a significant population trend over the last decade. However, based on the observed interannual variability, it is estimated that it would take 14 years to detect a trend equivalent to a 50 percent change over 10 years (Larned et al. 2001a). Current sampling intensity is too low to provide useful trend data for this very rare species. There is some support for the hypothesis that Steller's eiders have abandoned formerly occupied areas in eastern portions of the North Slope; if true, this likely indicates that the Alaska-breeding population is in decline.

Steller's eiders spend most of the year in marine habitats. During winter, most of the Steller's eiders concentrate along the Alaska Peninsula from the eastern Aleutian Islands to southern Cook Inlet in shallow, near-shore marine waters (Jones 1965, Petersen 1980). They also occur in the western Aleutian Islands and along the Pacific coast, occasionally to British Columbia, along the Asian coast (from the Commander islands to the Kuril islands), and some are found along the north Siberian coast west to the Baltic States and Scandinavia (Palmer 1976, Cramp et al. 1977). In spring, large numbers concentrate in Bristol Bay before migration; in 1992, an estimated 138,000 Steller's eiders congregated there before sea ice conditions allowed movement northward (Larned et al. 1994).

Steller's eiders arrive in pairs on the North Slope in early June. Nesting effort varies widely from year to year. In the years from 1991-2001, there were 6 "nesting years" (1991, 1993, 1995, 1996, 1999, 2000) when typical breeding activities occurred, and 5 "non-nesting years" (1992, 1994, 1998, 2001) when birds appeared in early summer, but no nests were found and Steller's eiders are believed not to have nested (Quakenbush et al. 1995, Obritschkewitsch et al., unpublished data). Four nests were found in 1997, but these were initiated late (early July) and none survived past mid-incubation (Service/North Slope Borough), unpublished data). The reasons for the observed variation in nesting effort are unknown, but an association has been noted between nesting years and years of lemming abundance. Nest success could be enhanced in years of lemming abundance, because predators are less likely to prey on eider nests when small mammals are abundant. It has also been hypothesized that avian predators such as pomarine jaegers (*Stercorarius pomarinus*) and snowy owls (*Nyctea scandiaca*), which nest at high densities only when lemmings are abundant, may provide protection for nearby eider nests incidental to defense of their nesting territories (Quakenbush and Suydam 1999). If this hypothesis is correct, the presence of avian predators is an essential element of breeding habitat.

In nesting years, initiation dates are typically in the first half of June (Quakenbush et al. 1995), and hatching dates range from 7 July to 3 August (Quakenbush et al. 1998). Nests in Barrow are located in wet tundra, in areas of low-center polygons or low (indistinct flat-centered) polygons, frequently within drained lake basins (Quakenbush et al. 1998). Average clutch sizes at Barrow ranged from 5.3-6.3 in 5 different years, with clutches up to 8 reported (Quakenbush et al. 1995). Nest success (proportion of nests at which at least 1 egg hatched) at Barrow averaged approximately 17 percent from 1991-2001 (Service, unpublished data). Egg loss was attributed mostly to predation by predators, including jaegers, common ravens (*Corvus corax*), and possibly glaucous gulls (*Larus hyperboreus*) and Arctic foxes (*Alopex lagopus*) (Quakenbush et al. 1995, Obritschkewitsch et al. 2001). The fledging period is not known, but is estimated to be 37 days (Obritschkewitsch et al. 2001). Broods most often used ponds with emergent grass (*Arctophila fulva*) (Quakenbush et al. 1998). Broods were reared close to their nest site; 8 broods tracked near Barrow in 1995 remained within 650m of their nest sites during the first 32 days after hatching (Quakenbush et al. 1998).

Males typically depart the breeding grounds after females begin incubating. Based on observations in the Barrow area, and on a small sample of birds equipped with satellite transmitters, males depart Barrow around the end of June or early July (Quakenbush et al. 1995, Obritschkewitsch et al. 2001). Both males and females tracked with satellite transmitters in a non-breeding year dispersed across the area between Admiralty Inlet and Wainwright in late June and early July, with most birds entering marine waters by the first week of July. The satellite-tracked birds used coastal locations from Barrow to Cape Lisburne, and made extensive use of lagoons and bays on the north coast of Chukotka (Service, unpublished data). Visual observations in other years confirm the use of nearshore areas of the Chukchi Sea; small groups of males (less than 10) have been observed in July near Barrow (Service, unpublished data). Females that fail in breeding attempts may remain near Barrow later in the summer; a single failed-breeding female equipped with a transmitter in 2000 remained near the breeding site until the end of July, and stayed in the Beaufort Sea off Barrow until late August. Females and fledged young depart the breeding grounds in early to mid-September.

In mid-August, Alaska-breeding Steller's eiders migrate to molting areas, where they congregate in large flocks in protected waters. Concentrations of molting Steller's eiders have been noted in Russia on the Chukchi and Bering sea coasts, near Saint Lawrence Island in the Bering Sea , and along the northern shore of the Alaska Peninsula (Kistchinski 1973, Fay 1961, Jones 1965, Petersen 1981). Satellite-tracked birds from Barrow molted at Nunivak Island, Cape Avinof (Kuskokwim Shoals), Nelson Lagoon/Port Moller, and Izembek Lagoon (Service, unpublished data).

Causes of suspected population declines are not known. Possible causes currently being examined include community dynamics of nesting avian populations in the Barrow area, artificial increases in predator populations on the North Slope, subsistence harvest and lead contamination.

ENVIRONMENTAL BASELINE

Regulations implementing the ESA (50 CFR §402.2) define the environmental baseline as the past and present impacts of all Federal, State, or private actions and other human activities in the action area. Also included in the environmental baseline are the anticipated impacts of all proposed Federal projects in the action area that have undergone Section 7 consultation, and the impacts of State and private actions, which are contemporaneous with the consultation in progress.

Status of Spectacled Eiders and Steller's Eiders Within the Action Area

Currently, no trend is discernible in spectacled and Steller's eider population sizes on the North Slope. Furthermore, the factors that limit population size on the North Slope have not been identified. Therefore, it is impossible to determine whether human activity and habitat alteration have affected the status of the species in the project area. However, factors that may have affected the status of the species in the project area include loss of breeding habitat, disturbance from oilfield operations, research efforts, lead contamination, increases in predator populations, and subsistence harvest.

Factors Affecting Species Environment Within the Action Area

Breeding habitat on the North Slope has remained largely unaltered and uninhabited by humans. A small portion of the species' potential breeding range has been altered by oil and gas development. Within the last decade oil and gas development has spread out from the coastal plain near Prudhoe Bay to offshore platforms in the Beaufort Sea to the borders of the Arctic National Wildlife Refuge in the east and the Colville River in the west. Since 1979, 7 OCS lease sales have been held and 30 OCS exploration wells have been drilled in the Beaufort Sea Planning Area. In 1999, the Service has completed Section 7 consultation on a development and production plan for the Northstar Project, which straddles Alaska State and Federal waters (Lease Sale 186 EIS). Northstar began production on October 31, 2001. The Service also completed consultation on a development and production plan for the Liberty Project, which is wholly located on the Federal OCS. A final EIS for the Liberty Project was published in May 2002. The applicant, BP Exploration (Alaska) Inc., announced that it has suspended work on the project pending a re-evaluation of project costs. The future of this project is uncertain. Impacts of oil development include construction, accidental spills of toxic materials, off-road vehicle use, wetland filling, and indirect effects of human presence in areas previously uninhabited.

Human population growth in the vicinity of Barrow and other North Slope communities has also resulted in localized habitat loss due to construction activities and off-road vehicle use. On-road and off-road vehicle traffic are potential sources of disturbance. Steller's eider research conducted jointly by the Service and North Slope Borough is also a source of disturbance, because those activities are oriented toward locating nests and broods. One nest was depredated in 2000 as a likely result of nest-search disturbance, when a nest was left exposed to a jaeger because of the proximity of the researcher (Service, unpublished data). Nest abandonment, in the absence of predation, has only been documented as a result of research-related trapping and handling of an incubating hen; it is possible, however, that chronic human disturbance close to a nest could cause abandonment.

Lead or other sources of contamination of habitat or prey species are possible in localized areas within the range of Steller's and spectacled eiders. Exposure of waterfowl to lead has been documented in the range of the Alaska-breeding population of Steller's eiders. Elevated blood and tissue lead levels, morbidity, and mortality from lead poisoning were found in spectacled and common eiders (*Somateria fischeri* and *S. mollissima*, respectively) on the Yukon-Kuskokwim Delta (Franson et al. 1995, Flint et al. 1997, Flint and Herzog 1999). On the breeding grounds near Barrow, one Steller's eider found dead in June had liver and kidney lead concentrations suggestive of lead poisoning, although several other Steller's eiders examined at the same time of year had lower lead tissue concentrations (Trust et al. 1997, Service, unpublished). Blood samples from nesting hens trapped near Barrow in 1999 and 2000 showed that all (8 of 8) had concentrations exceeding the clinical threshold for lead exposure and 7 of 8 exceeded thresholds for lead poisoning in waterfowl.

Often, with increases in human presence, there is a concomitant increase in nest predator populations such as gulls, ravens, and foxes. Residents of Barrow and other North Slope communities have observed an increase in populations of gulls and arctic foxes. There is very little information on predation of Steller's and spectacled eider nests throughout most of the species' range in Alaska. Near Barrow, however, Steller's eider nest success in recent years has been very poor. Of 186 nests found from 1991-2000, only 15-18 percent survived until hatching, with predation thought to be the primary factor causing nest failures (Quakenbush et al. 1995, Obritschkewitsch et al. 2001). In addition to causing complete nest failures during incubation, predators at Barrow further reduced productivity through partial predation (where some but not all eggs in a nest were taken) and by killing ducklings that survived the incubation period (Quakenbush et al. in prep.). Studies of nest predation in other areas have reported mixed results. For example, "apparent" nest success on the Indigirka River Delta, Russia in 1971 was 10-15 percent, and eiders nesting near gull nests had higher nesting success (Kistchinski and Flint 1974, Mayfield 1975). However, in 1994 nest success was <2 percent and nest predators such as Arctic foxes, glaucous and herring gulls, and parasitic and pomarine jaegers are suspected to have depredated most of the nests (Pearce et al. 1994). Also, nearly complete predation of spectacled eider nests by jaegers and foxes was recorded on the Chaun River Delta, Russia after a June snow storm (Kondratev and Zadorina 1992). Predation by gulls, jaegers, and Arctic foxes probably affects the survival of Steller's and spectacled eider eggs and ducklings throughout the species' range.

Sport hunting for Steller's and spectacled eiders was closed in 1991 by Alaska State regulations and Service policy. Outreach efforts have been conducted by the North Slope Borough and Service to inform hunters of these closures. Accurate information on current harvest rates is not available, but hunter surveys and other observations indicate that hunting of Steller's and spectacled eiders likely continues in Northwest Alaska (Paige et al. 1996, Georgette 2000, Wentworth 2001).

Conservation efforts also affect spectacled eiders and their habitat within the action area. The Service provides project applicants with recommendations and restrictions intended to minimize impacts of oilfield activities on spectacled eiders. These include timing restrictions and buffers around known nest sites and likely benefit spectacled eiders at the individual level.

All of the factors discussed here may have influenced populations of spectacled and Steller's eiders in northern Alaska, although it is unknown if these factors played a major role in either species' decline.

EFFECTS OF THE ACTION ON LISTED SPECIES

Helicopter Overflights

Nesting Steller's and spectacled eiders could be disturbed by helicopter overflights related to exploration and delineation activities. However, disturbance to nesting spectacled and Steller's eiders is unlikely due to their extremely low densities across the North Slope. Across the Arctic Coastal Plain of the North Slope, breeding season density averages approximately one pair per 8 km^2 for spectacled eiders (Larned et al. 2002a). Steller's eiders are so rare in some years that they are not detected at all by aerial survey methods. In the core Steller's eider breeding area near Barrow, the highest density recorded in 4 years of aerial surveys was estimated as approximately one pair per 12.5 km (Ritchie and King 2002). Densities elsewhere on the Arctic Coastal Plain are much lower, and may approach zero.

The number of helicopter trips flown in support of exploration- and delineation-well drilling is assumed to range from about 90-270 each year, depending on the number of wells (1-3) that are drilled. For each drilling operation, it is assumed that there would be one flight per day of drilling. The time required to drill and test a well is about 90 days. Most flights will transport employees between Deadhorse and as yet unspecified exploration sites.

Heavy helicopter traffic could adversely affect spectacled eiders by: 1) displacing adults and/or broods from preferred habitats during pre-nesting, nesting, brood rearing and migration; 2) displacing females from nests, exposing eggs or small young to inclement weather or predators; and 3) reducing foraging efficiency and feeding time. The behavioral response of eiders to aircraft overflights is unknown; some spectacled eiders nest and rear broods near the Deadhorse Airport, indicating that some individuals may tolerate frequent aircraft noise. Individual tolerances are likely to vary, however, and the intensity of disturbance associated with the proposed action would, in some cases, be greater than that experienced by birds near the airport. Some birds may be displaced, with unknown physiological and reproductive consequences. The number of eiders that would be exposed to helicopter overflights is variable, however. This is, in part, because the potential flight paths to drilling sites within the Lease area could range from short (e.g., a direct route from Deadhorse to Beaufort Sea) to lengthy (e.g., a flight path to a remote site 25 mi. north of Barrow). Because most oil exploration and development in the Lease Sale 186 area is anticipated to occur in the Near and Mid Zone areas close to primary support facilities at Deadhorse and vicinity, spectacled eiders in the Deadhorse area are much more likely to be overflown than those in more distant portions of the lease area.

In conclusion, while helicopter overflights potentially could cause adverse effects to individuals of either species of listed eider, their low nesting densities and low use of nearshore areas during migration, suggest that few individuals would likely be impacted. Likewise, the wide range of tolerances found in individual birds to this type of potential disturbance make it difficult to predict whether adverse impacts would actually occur. Finally, the EIS indicates that the most likely locations for exploration are in the Near and Mid zones. Steller's eiders are extremely rare in these zones, and the probability of affecting large numbers is diminished because of the relatively short flight paths.

Onshore Bases and Pipelines

Disturbance to Steller's and spectacled eiders from onshore bases and pipelines is also possible. The level of disturbance anticipated is highly variable depending on the zone within the OCS within which future development actually occurs. For the Near Zone, an area anticipated to receive over 70 percent of all development, MMS expects that no new landfalls, shore bases, or new onshore processing facilities would be required. For development within the Mid- and Far Zones, projects could involve new pipeline landfalls and shore bases. Because the Mid- and Far Zones are mostly beyond the influence of existing infrastructure on the North Slope, new development projects could introduce significant changes to the level of disturbance experienced at landfall areas. The MMS's Lease Sale 186 EIS states that route selection and installation of offshore pipelines could occur either in the summer open-water season or during mid- to late winter when landfast ice has stabilized. New onshore pipeline sections would be constructed simultaneously with the offshore pipeline installation. Because onshore pipelines and support bases may be constructed during the summer breeding season, there is potential for disturbance to nesting spectacled eiders. Observations from Prudhoe Bay suggest that spectacled eiders exhibit some tolerance of facilities (including pipelines) and service roads (TERA 1996). Telemetry studies in 1993 and 1994 showed broods spending time within 200 m (656 feet) of facilities, and crossing roads (five known broods in 1995 and two in 1994).

The development of onshore bases and pipelines would only occur in support of oil production and thus is not a part of the leasing and exploration action being considered in this incremental consultation other than with regard to the jeopardy determination. Although construction and operation of onshore bases may displace and/or disturb individual eiders, the total area affected is not expected to result in population-level impacts. If onshore bases and additional pipelines to transport produced oil and gas are proposed in the future, the impacts of those actions would be fully considered when consultation is requested on that increment of the OCS program.

Exploration, Production and Support Activity

Encounters between marine seismic equipment, offshore drilling, dredging, and vessels involved in ice breaking and threatened eiders at sea is also a possibility. During the open-water season, MMS assumes various levels of seismic-survey activity and supply boat support. Site-specific surveys of the exploration and delineation well sites would be conducted during the ice-free seasons of the years of the exploratory phase. The MMS estimates each survey would cover roughly 23 square kilometers for each exploration well and last between 2 and 5 days. The annual number of supply boat trips per open-water season could be as high as 14.

If exploration occurs between October and May, the probability of exploratory activities (not including accidental discharge of oil) in the Beaufort Sea resulting in encounters with spectacled or Steller's eiders would be low. This probability increases, however, if the action occurs between May and October because of the presence of spectacled and Steller's eiders migrating across the Chukchi and Beaufort seas to reach breeding grounds in the spring and when migrating to molting/staging areas in the summer and fall.

Extensive nearshore and offshore aerial surveys in the Beaufort Sea in 1999 and 2000 failed to detect concentrations of spectacled eiders (no Steller's eiders were observed), except for two flocks (numbering 40 and 100) offshore in the Harrison Bay area (Fischer at al. 2002). Given the rarity of these species, we assume that few threatened eiders would encounter vessel traffic. We surmise that eiders would avoid such encounters by diving or flying away, that the frequency of those disturbances will not reach the threshold that would impair survival, and that alternative suitable habitat is available. Under these conditions, take is unlikely, and would not reach a population-level effect.

Collisions with Drilling Structures

Migrating birds are at risk of collision with objects in their path, particularly when visibility is impaired during darkness or inclement weather, such as rain, drizzle, or fog (Weir 1976). The incidence of bird strikes appears to rise when objects are illuminated with constant diffuse light, and the tendency for birds to be drawn to diffuse light appears to increase during rainy or foggy weather. Accidental strikes of "hundreds" of unidentified eiders were reported to have occurred in association with the Bering Sea crab fishery, presumably influenced by the bright lights used on fishing vessels (Service 1996). Comparisons have shown that blinking lights cause less mortality than constant lighting, and the color of the lights and the object may influence collision frequency (Weir 1976). Cross-sectional area also affects the number of birds that strike an obstruction.

Johnson and Richardson (1982) reported that 88 percent of eiders flew below an estimated altitude of 10 m (32 feet) and well over half flew below 5 m (16 feet). Recently, (September/October 2001) several sea duck fatalities as a result of platform strikes were documented at Northstar Island, a production platform within the Lease Sale 186 area. In 2001,18 birds were retrieved at Northstar Island, all sea ducks, including 4 king eiders, 6 common eiders, and 8 long-tailed ducks (Service, unpublished). The densities of Steller's and spectacled eiders on the North Slope are much lower than those of the species found dead at Northstar. Therefore the potential for them striking OCS oil platforms is much lower. Although information specific to spectacled eider flight behavior is lacking, a spectacled eider was seen striking a utility wire near an electric light in white-out conditions on St. Lawrence Island in 1998 (Service, unpublished).

Several structures associated with exploration and delineation wells may pose a risk to migrating eiders, including crane boom, drilling rigs, and other buildings. Although the total profile of exploratory and delineation wells and associated structures is small relative to the Beaufort Sea, the Service believes that the structures pose a risk to migrating eiders, including spectacled and possibly Steller's eiders, because: 1) the Lease Sale186 area contains the "main route" used by female eiders migrating west through the Beaufort Sea, speculated to be "just north of the barrier islands" (Johnson and Richardson 1982); 2) the artificial lighting associated with drill rigs may serve as a magnet to migrants, particularly during fog and rain (Weir 1976); and 3) the flight altitude of migrating eiders is low and within the height range of exploration and production facilities.

It is estimated that 47 percent of the North Slope spectacled eider population breeds to the east of Barrow, and it is a reasonable (though unproven) assumption that birds breeding west of the project infrastructure do not wander eastward (Service, unpublished). The likelihood of death or injury as a result of collision is diminished because recent radio telemetry studies have shown that few male spectacled eiders migrate through the Beaufort Sea on their way from their North Slope breeding grounds to molting/staging areas in the Chukuchi Sea (TERA 2002 review). Females nesting east of Barrow have been shown to utilize the western regions of the Beaufort Sea extensively en route to molting/staging areas (TERA 2002, review). Therefore, based on our understanding of the biology of the species, their migration routes, distribution, and behavior, we believe that there is some risk of injury or death of some individuals from collisions with oil and gas exploration and delineation structures. However, the best available scientific and commercial information does not lead us to believe that significant population-level impacts are likely to result from the proposed action.

Increase in Predator Populations

Several North Slope predators that prey on waterfowl eggs and young concentrate in areas where anthropogenic food sources are made available. Examples include glaucous gulls, ravens, and Arctic foxes that are abundant near camps, roads, oilfields, and villages. For ravens and foxes, there is evidence showing population increases and/or changes in distribution in response to anthropogenic food sources, and the breeding distribution of ravens has expanded on the North Slope because buildings and other structures in oil developments provide nesting sites (Day 1998). The predation pressure that foxes and, to a lesser degree, gulls and ravens, exert on ground-nesting birds is also well documented, and in some areas predation may be the single most important factor affecting nest success (ibid.).

Spectacled and Steller's eiders may be adversely affected by increased numbers or distribution of predators. Ravens apparently never successfully nested in Barrow until 1991 when a single pair began raising a brood each year on a man-made structure. In 1991, one of these ravens was seen depredating five eggs from two Steller's eider nests (Quakenbush et al. 1995). Although information showing a direct link between oilfield activities and waterfowl nest predation rates is lacking, the Service believes that actions that artificially enhance predator populations are a potential adverse impact to listed eiders.

The development of significant permanent infrastructure would only occur in support of oil production and thus is not a part of the leasing and exploration action being considered in this incremental consultation other than with regard to the jeopardy determination. If permanent infrastructure is proposed in the future, the impacts of those actions would be fully considered when consultation is requested on that increment of the OCS program including their potential impacts on predator populations. Based on the limited number and ephemeral nature of exploratory drilling rigs, we do not believe that these will affect predator populations sufficiently to cause impacts to threatened eiders on the population level.

Oil Spills

Spilled oil can have significant impacts on birds. Exposure to oil can affect birds in several ways. Most birds exposed to oil die within a short period of time, often through loss of the insulative properties of their plumage so that hypothermia ensues (Hunt 1987, Piatt et al. 1990). Embryos or young can be killed by contact with adults that have oiled plumage (King and Lefever 1979, Peakall et al. 1982). Birds that ingest contaminated food can suffer fatal toxicological effects (Peakall et al. 1983). Species that feed on invertebrates or other organisms that bioaccumulate and/or biomagnify toxins are particularly vulnerable.

Oil spills and associated clean-up could result from the proposed project. Potential sources of a spill include a drilling blowout, failure of diesel fuel storage tanks on exploratory islands, rupture of pipelines (loss > 0.15 percent of flow rates), chronic leaks from the pipelines (loss < 0.15 percent of flow rate), or spills from barges or trucks used to transport fuel oil to exploratory and delineation rigs. Historical data from North Slope oil production show that between 0 and 102 spills per year occurred from 1970-1997; most were small spills, as mean spill size in all years was <100 bbl (Lease Sale 186 EIS). Small spills, although the most likely, have the least impact to wildlife populations because a smaller area is affected and fewer individuals are likely to be exposed. Similarly, spills in the terrestrial environment, though possible, will likely have minimal impact because the density of Steller's and spectacled eiders is relatively low in the project area and spills on land spread slowly and will be more easily detected and contained. Therefore, the Service considers the possible impacts from small marine spills and spills in the terrestrial environment to be unlikely to affect more than a few individual Steller's and spectacled eiders. Thus, the remainder of this discussion will focus exclusively on medium or large (≥1,000 bbl [42,000 gal]) spills in the marine environment.

The expected impacts of oil spills depends on how accurately spill characteristics, as well as the distribution and behavior of the birds are predicted. Estimating the probability of spills is fundamental: if no oil is spilled, there will be no impacts. If one or more spills occur, characteristics such as volume, trajectory, and timing will greatly influence the impact on eiders. Patterns of use of the Beaufort Sea by Steller's and spectacled eiders are equally relevant. Evaluating the likelihood of spills from exploration and delineation is constrained by the small number of comparable projects in the Beaufort Sea. The Lease Sale 186 EIS estimated that the risk of one or more spills of at least 1,000 bbl (42,000 gal) over the life of the project is 8-10 percent. Oil-Spill-Risk Analysis modeling within the Lease Sale 186 EIS estimates that if such a spill does occur the chance that listed eiders will come in contact with spilled oil in nearshore or offshore areas ranges up to 55 percent in summer; along the shoreline contact probability is less than 8 percent. No estimates of spill risk from barges or trucks used to transport fuel oil to exploratory and delineation sites were given in the Lease Sale 186 EIS.

Cleanup of a spill in the Beaufort is anticipated to be limited by ice and weather conditions in the area. In many cases, final cleanup of an oil spill may only be possible from early July through August after the Lease Sale 186 area is ice free (National Research Council 1994). Because of unstable and broken ice conditions in the area, once a leak is detected, response for containment and cleanup of a spill will be delayed or hindered during 6 months of the year, and then only as weather permits. In addition, historical recovery rates of spilled oil are traditionally very low even when cleanup is not hampered by Arctic weather and frozen or partially frozen seas. Based on national and international data, recovery rates of 20-25 percent are considered high and are usually not above 10 percent (Alaska Department of Environmental Conservation 1998, National Research Council 1994).

Oil spill response activities such as hazing and other human activities (boat and air traffic) could also impact spectacled eiders. Hazing, according to the Lease Sale 186 EIS, may have limited success during spring when migrants occupy open water in ice leads. The hazing effect of cleanup activity or actively hazing birds out of ice leads that oil is expected to enter may be counterproductive, because there are few alternative habitats that flushed birds can occupy. Cleanup activities in leads during May and open water in July through September are likely to adversely affect spectacled eiders.

In summary, accidental oil spills can have significant impacts on birds as a result of direct and indirect contact. Potential sources of a spill include a drilling blowout, failure of diesel fuel storage tanks on exploratory islands, rupture of pipelines, chronic leaks from the pipelines, or spills from barges or trucks used to transport fuel oil to exploratory and delineation rigs. Small spills are the most likely to occur but that also have the least potential impact to listed species because a smaller area is affected and fewer individuals are likely to be exposed. Similarly, spills in the terrestrial environment will likely have minimal impact because the density of Steller's and spectacled eiders is relatively low in the project area and spills on land spread slowly and will be more easily detected and contained. Large spills (≥1,000 bbl [42,000 gal]) spills in the marine environment are of a greater concern, however, the risks during exploration and delineation are significantly less than during production, which the EIS indicates is 8-10 percent over the life of the proposed project. The probability of a large oil spill contacting a significant number of spectacled or Steller's eiders is further diminished by considerations of timing, ice and weather conditions, effectiveness of spill response, and the dispersed nature of the birds' distribution. The coincidence of all those factors which would have to occur simultaneously in order to appreciably reduce the likelihood of survival and recovery is improbable. Thus, we conclude that such an impact is not reasonably certain to occur.

Toxics Contamination

Leasing and exploration may also result in increasing contamination of marine habitats, due to the disposal of drilling muds and cuttings, or accidental eruption of oil from test wells during a blowout. Such contamination may impact individuals either through direct contact or indirectly as a result of effects on prey populations or important habitats. Information provided by the MMS indicates that industry's record on the Outer Continental Shelf allows the assumption of a probability of crude-oil release during exploration to be zero, however the potential for such an occurrence exists.

The Lease Sale 186 scenario developed by the MMS, which this opinion will assume, indicates that 6 exploration and 6 delineation wells are expected to be drilled during the period 2004 through 2010. A maximum of two drilling rigs would be operable in any one exploratory year, assuming one exploration rig per platform. Discharges as a result of these wells are regulated by the Environmental Protection Agency through a National Pollutant Discharge Elimination System (NPDES). The EPA initiated consultation with the Service in January 1994 to determine the likelihood that the proposed discharges associated with exploratory drilling would adversely affect listed species. The Service concurred with the EPA that the proposed NPDES permit issuance would not be likely to adversely affect listed species. Therefore, the EPA and MMS have already satisfied the requirements of the

Endangered Species Act regarding effluent discharges associated with oil and gas exploration in the Beaufort and Chukchi seas (State and Federal waters).

CUMULATIVE EFFECTS

Cumulative effects include future State, local or private actions that are reasonably certain to occur in the action area considered in this biological opinion. Future Federal actions that are unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to Section 7 of the Act.

State or private actions reasonably certain to occur within or near the proposed sale area would include: State of Alaska oil and gas lease sales, exploration, development, and production; gravel mining, support facility and road construction to support these activities as well as pipelines and related oil and gas transport facilities, including feeder lines, Trans-Alaska Pipeline operation and maintenance; possibly some future Canadian Beaufort Sea oil and gas activities; land reconveyances from Native corporations to private individuals; subsistence harvest activities; commercial fishing; marine shipping; and recreational activities.

CONCLUSION

After reviewing the proposed action, the current status of spectacled and Steller's eiders, the environmental baseline for the action area, the effects of the proposed action, and the cumulative effects, it is the Service's biological opinion that Beaufort Sea Oil and Gas Lease Sale 186 and associated activities, as proposed, are not likely to jeopardize the continued existence of the spectacled and Steller's eider. There is no designated or proposed critical habitat on the North Slope for spectacled or Steller's eiders.

Regulations (51 FR 19958) that implement Section 7(a)(2) of the Act define "jeopardize the continued existence of" as "to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species." In evaluating the impacts of the proposed Lease Sale 186 to Steller's and spectacled eiders, the Service identified a series of direct impacts that could result, such as disturbance from helicopter overflights, collisions with drill rig facilities by migrants, and changes in the number or distribution of predators. However, the Service believes that the combined impacts to spectacled and Steller's eiders through these avenues will be minimal for the reasons given in the *Effects of the Action* section of this biological opinion. The widely dispersed nature of these two species, both onshore and offshore in the Beaufort Sea region, reduces their vulnerability to perturbations of limited geographic scope.

The Service believes that the greatest risk to listed species from the proposed Lease Sale 186 is potential impacts from accidental oil spills in the marine environment. However, as noted above, for the project to jeopardize the continued existence of spectacled eiders, an appreciable reduction in the likelihood of both the survival and recovery of one or both species must be "reasonably expected to occur." Thus, when determining whether possible oil spills jeopardize listed species, the Service must consider the following: 1) the likelihood of one or more spills occurring; and 2) if one or more spills occur(s), the likelihood that the spill(s) will kill enough spectacled eiders to appreciably reduce their likelihood of survival and recovery.

The likelihood of one or more large spills $\geq$1,000 bbl in size occurring during the lifetime of Lease Sale 186 is estimated to be 8-10 percent. Assuming factors similar to Northstar, the likelihood of a very large spill (blowout) $\geq$150,000 bbl in size occurring during the lifetime of Lease Sale 186 is 9.4×10^{-7}. However, the impacts of a spill to biological resources (e.g., eiders) vary with spill volume, spill trajectory, whether the resource is present during the time of year that spilled oil is present, and the length of time that oil persists in the environment. This is exemplified by Stehn and Platte's (2000) model, which estimated mortality from a 30 day spill in July caused by exploratory activity within the Lease Sale 186 area at 2-52 spectacled eiders. While if a 30 day spill were to occur throughout August during the period of active westward migration, mortality resulting from a large spill is estimated to be $\leq$100 individuals. Although the estimates of spill probability and impacts to threatened eiders are constrained by lack of information on oil development, subsea pipeline safety, and numbers/locations of threatened eiders in the region, the available information leads the Service to conclude that an appreciable reduction in the likelihood of survival and recovery of listed eiders is not reasonably expected to occur.

INCIDENTAL TAKE STATEMENT

Section 9 of the Act and Federal regulation pursuant to section 4(d) of the Act prohibit the take of endangered and threatened species, respectively, without special exemption. Take is defined as to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture or collect, or attempt to engage in any such conduct. "Harm" is further defined by the Service to include significant habitat modification or degradation that results in death or injury to listed species by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. "Harass" is defined by the Service as intentional or negligent actions that create the likelihood of injury to listed species to such an extent as to significantly disrupt normal behavior patterns, which include, but are not limited to, breeding, feeding or sheltering. Incidental take is defined as take that is incidental to, and not the purpose of, the carrying out of an otherwise lawful activity. Under the terms of section 7(b)(4) and section 7(o)(2), taking that is incidental to and not intended as part of the agency action is not considered a prohibited taking provided that such taking is in compliance with the terms and conditions of this Incidental Take Statement.

The measures described below are non-discretionary, and must be undertaken by MMS so that they become binding conditions of any grant or permit issued to an applicant, as appropriate, for the exemption in section 7(o)(2) to apply. The MMS has a continuing duty to regulate the activity covered by this Incidental Take Statement. If the MMS fails to assume and implement the terms and conditions or fails to require any applicant to adhere to the terms and conditions of the Incidental Take Statement through enforceable terms that are added to the permit or grant document, the protective coverage of section 7(o)(2) may lapse. In order to monitor the impact of incidental take, the MMS must report the progress of the action and its impact on the species to the Service as specified in the Incidental Take Statement. [50 CFR 402.14(i)(3)]

Helicopter Overflights

Disturbance from helicopter overflight to Steller's and spectacled eiders is unlikely because over most of the lease area, there is a low probability that the few areas occupied by scattered flocks during the spring to fall staging and migration periods would be overflown routinely by support aircraft flying between a few offshore drill sites and onshore facilities. A potential exception might be spectacled eiders occurring in coastal or offshore portions of the Near Zone or western Midrange Zone areas that are relatively close to primary support facilities at Deadhorse. Eiders in this vicinity may be more likely to be overflown than those in the more distant portions of the lease area. However, few eiders remain for long in marine waters in the immediate vicinity of Prudhoe Bay and therefore disturbance would be minimal (TERA 1997, 1999).

As described in the *Effects of the Proposed Action* above, spectacled and Steller's eider adults and/or broods may occur below or adjacent to helicopter routes. However, the Service does not anticipate that helicopter flights associated with Lease Sale 186 will result in take of spectacled or Steller's eiders due to low recorded densities of breeding and migrating spectacled eiders in the project area and observed tolerance of nesting spectacled eiders to overhead flights near Deadhorse airport.

Exploration, Production and Support Activity

Because Steller's eiders using the marine environment rarely occur in the Near or Midrange Zones from Harrison Bay east, where 90 percent of the Lease Sale 186 leasing activity and development projects are expected to occur, it is unlikely that the action will generate major disturbance. Because of the large amount of nearshore habitat available to spectacled eiders in the Beaufort Sea, spectacled eiders staging or migrating in offshore water are not likely to experience significant disruption of foraging or displacement as a result of routine exploration, development, or support activities during the open-water season.

Despite potential encounters with exploration and support activities at sea, eiders typically avoid such encounters by diving or flying away from such disturbance. Substantial adverse effects on spectacled or Steller's eiders resulting from offshore marine activities in the vicinity of the proposed area of the action are unlikely. Therefore, the Service does not anticipate that disturbance from exploration, production and support activity will result in take of spectacled or Steller's eiders.

Collisions with Drilling Structures

The Service anticipates that some level of take of spectacled and/or Steller's eiders may result from collisions with exploratory, delineation and production drilling structures. Such losses may affect the regional population of spectacled eiders, which shows a non-significant downward trend in the past decade, and Steller's eiders, which shows a nonsignificant upward trend over the same time period. However, the MMS's uncertainty over locations, number and size of drilling platforms within Lease Sale 186 makes quantifying potential bird strikes difficult. Also, limited information available on spectacled and Steller's eider migration routes, behavior, and vulnerability to obstructions when migrating further complicates estimating anticipated take. However, the anticipated footprint of all exploratory and production platforms is likely to be relatively small within the Lease Sale 186 area (3.95 million hectares) and the majority of eiders encountering platforms during migration are likely to miss or avoid the obstruction.

Estimating incidental take of Steller's and spectacled eiders from strikes is extremely difficult due to a lack of available information on sea duck strikes coupled with uncertainty over potential numbers, locations, seasonality and duration of potential Beaufort OCS activities. Limited data is available for common eider (*Somateria mollissima v-nigra*) strikes to Northstar Island, which is located within the Lease Sale 186 area. From this data it is possible to generate a generic strike rate for sea ducks per well-year by dividing the number of common eider strikes (6) to Northstar Island in 2002 by the most recent population estimate of common eiders migrating west over the Beaufort Sea (111,635) (Suydam et al. 1996, Service, unpublished). That number is then multiplied by the North Slope population estimates for spectacled (7,370) and Steller's eiders (433) (Larned et al. 2001a) to give a "strikes per well year" estimate for both species. The results of this methodology indicate that 0.40 spectacled and 0.02 Steller's eiders will be taken per well-year as a result of colliding with drill rigs and/or other exploratory and delineation structures.

The Lease Sale 186 EIS states that no more than two drilling rigs would operate at any time, with a total of 6 exploration and 6 delineation wells expected to be drilled over a 7-year exploration period. Therefore, the Service anticipates that the maximum number of exploration and/or delineation wells drilled within the Beaufort Sea resulting from the MMS's Lease Sale 186 would be twelve. Twelve wells result in 12 well-years, from which we estimate take of five spectacled and one Steller's eider over the life of the proposed leases.

It is important to note that the above estimates for incidental take from strikes to drill rigs are crude. The estimates do not take into consideration that eider strikes are episodic in nature, many spectacled and most Steller's eiders never migrate through the Beaufort Sea, and that the strike rates are generated from only 1 year of data at a single location in the Lease area. Therefore, as more data on eider strikes to OCS platforms in the Beaufort Sea becomes available, the MMS may need to reinitiate consultation if observed strike rates are higher than the above anticipated incidental take level.

Increase in Predator Populations

State of Alaska, Department of Environmental Conservation regulations that govern refuse management in oilfields include provisions to make it illegal for any person to intentionally feed wildlife or leave human food or garbage in a manner that attracts wildlife [5 AAC 92.230]. The Service assumes that the applicant will completely comply will all applicable regulations governing waste management, and therefore anticipates that no incidental take of listed eiders will result from an increase in predator abundance caused by improper waste management.

Oil Spills

If a large oil spill occurred in the location of and during spectacled eider presence, spectacled eider mortality likely would be ≤100 individuals; however, any substantial loss (25+ individuals) would represent a significant effect (MMS Lease Sale 186). It is unlikely that take of Steller's eiders will result from a large oil spill in late spring or in early summer unless atmospheric and oceanic conditions were such that spilled oil dispersed towards Barrow and into the Chukchi Sea. The MMS's Lease Sale 186 Oil-Spill-Risk-Analysis modeling runs predict the probability of such a spill scenario to be very low.

Extent of take that will result from oil spills from the proposed action is extremely difficult to estimate. First, it is uncertain that oil will be spilled. As stated in the biological evaluation, the likelihood of at least one spill of at least 1,000 bbl (42,000 gal) during the life of the project (~26 years) is currently estimated to be 8-10 percent. In the unlikely event of such an oil spill, the extent of take will be greatly influenced by the number, volume, trajectory, and timing of spills as well as the period that oil remains in the environment. In addition, the low probability of such an event, combined with the uncertainty of the location of the spill, and the seasonal nature of the resources inhabiting the area, make it highly unlikely that a large oil spill would contact a threatened eider. Spectacled and Steller's eiders are present on the North Slope for only 3-5 months out of the year. Even if an eider were present in the vicinity of an oil spill, it might not be contacted by the oil due to avoidance behavior, ice conditions or weather patterns. Furthermore, the MMS requires companies to have and implement oil-spill-response plans to help prevent oil from reaching critical areas and to remove oil from the environment. Therefore, the probability of a large oil spill contacting a Steller's or spectacled eider is much less than 8-10 percent over the 30 year life of the proposed leases (2003-2033).

Considering the low probability of a large spill coupled with a variety of other factors that would need to satisfied to result in take, the Service anticipates that it is highly unlikely that incidental take of listed eiders will result from oil spills within the Lease Sale 186 area. However, should any oil spill within the Lease Sale 186 area result in the take of any Steller's or spectacled eider, the MMS will immediately cease all operations responsible for the take pending reinitiation.

Toxics Contamination

The EPA initiated consultation with the Service in January 1994 to determine the likelihood that the proposed discharges associated with exploratory drilling would adversely affect listed species. The Service concurred with the EPA that the proposed NPDES permit issuance would not be likely to adversely affect listed species. Therefore, the EPA and MMS have already satisfied the requirements of the Endangered Species Act regarding effluent discharges associated with oil and gas exploration in the Beaufort and Chukchi seas (State and Federal waters). The Service anticipates that no incidental take of listed eiders will result from an increase in discharges associated with exploratory drilling.

Conclusion

In conclusion, the Service anticipates the proposed action will likely result in the take of five spectacled and one Steller's eiders over the life of the lease sale as a result of bird collisions with exploratory and delineation structures. The take is expected to be in the form of killing. In the accompanying Biological Opinion, the service determined that this level of anticipated take is not likely to result in jeopardy to the species or destruction or adverse modification of critical habitat.

While the incidental take statement provided in this consultation satisfies the requirements of the Act, as amended, it does not constitute an exemption from the prohibitions of take of listed migratory birds under the more restrictive provisions of the Migratory Bird Treaty Act. However, the Service will not refer the incidental take of any migratory bird or bald eagle for prosecution under the Migratory Bird Treaty Act of 1918, as amended (16 U.S.C. §§ 703-712), or the Bald and Golden Eagle Protection Act of 1940, as amended (16 U.S.C. §§ 668-668d), if such take is in compliance with the terms and conditions (including amount and/or number) specified herein.

Reasonable and Prudent Measures

The Service believes that the following reasonable and prudent measures are necessary and appropriate to minimize take of Steller's and spectacled eiders: to minimize the likelihood that migrating spectacled or Steller's eiders will strike exploration or delineation structures, the MMS and the Service will cooperatively develop a lighting protocol intended to reduce radiation of light outward from structures and to increase the visibility of structures to migrating eiders.

Terms and Conditions

In order to be exempt from the prohibitions of Section 9 of the Act, the MMS must comply with the following terms and conditions, which implement the reasonable and prudent measures described above and outline required reporting/monitoring requirements. These terms and conditions are non-discretionary.

To minimize the likelihood that migrating spectacled or Steller's eiders will strike structures associated with exploration and delineation drilling, the MMS and Service will cooperatively develop a lighting protocol to be used on exploration and delineation structures and identify where and when the protocol should be applied. The lighting protocol will contain the following two components:

1. The radiation of light outward from exploration/delineation structures will be minimized. This will be achieved by shading and/or light fixture placement to direct light inward and downward to living and work surfaces while minimizing light radiating upward and outward.

2. Structures will be lighted and/or marked to improve visibility to migrants according to a strategy to be jointly developed by the MMS and the Service.

a) This strategy will be developed using available information on bird avoidance measures including, but not limited to, results of the ongoing study of lighting regimes for Northstar Island being conducted by BP Alaska, ABR, Inc., and the Service.

b) A draft strategy will be provided by the Service to MMS by December 31, 2003; the final strategy must be mutually agreed upon by the MMS and Service by April 1, 2004, or a later date that is mutually agreed upon.

c) This strategy applies to all exploratory and delineation structures used after April 1, 2004, because bird avoidance measures that provide unequivocal benefits are not available at this time.

d) Any lighting requirements resulting from strategy need not apply between October 31 and May 1, because listed eiders are not thought to be present in the Beaufort Sea during this period.

e) This strategy will be modified, as appropriate, if significant new information on bird avoidance measures becomes available during activities covered by this consultation. Modifications to the strategy will be developed jointly by MMS and the Service.

The Service believes that no more than five spectacled eider and one Steller's eider will be incidentally taken during the life of the proposed project. The reasonable and prudent measure, with its implementing term and condition, is designed to minimize the impact of incidental take that might otherwise result from the proposed action. If during the course of the action, this level of incidental take is exceeded, such incidental take represents new information requiring reinitiation of consultation and review of the reasonable and prudent measure provided. The Federal action agency must immediately provide an explanation of the causes of the take and review with the Service the need for possible modification of the reasonable and prudent measure. If Steller's and/or spectacled eiders are encountered injured or killed through collisions with exploration and delineation structures, please contact the Fairbanks Fish and Wildlife Field Office, Endangered Species Branch, Fairbanks, Alaska, at (907) 456-0499 for instruction on the handling and disposal of the injured or dead bird.

CONSERVATION RECOMMENDATIONS

Section 7(a)(1) of the Act directs Federal agencies to utilize their authorities to further the purposes of the Act by carrying out conservation programs for the benefit of endangered and threatened species. Conservation recommendations are discretionary agency activities to minimize or avoid adverse effects of a proposed action on listed species or critical habitat, to help implement recovery plans, or to develop information. We recommend the following actions be implemented during the leasing and exploration phase of this lease sale:

1. The MMS should work with the Service and other Federal and State agencies in implementing recovery actions identified in the spectacled and Steller's eider recovery plans. Research to determine important habitats, migration routes, and wintering areas of spectacled and Steller's eiders would be an important step toward minimizing conflicts with current and future oil and gas development activities.

2. The Service believes that having oil industry employees recognize the presence of listed species during activities associated with exploration would allow the employee to take measures to minimize disturbance and avoid unauthorized incidental take. To this end, the MMS should work with the Service to produce, and work with the industry, to disseminate wallet-size information cards to company and contract employees. Dissemination of cards would preferably occur at employee orientations required in Stipulation 2 of the Lease Sale 186 EIS. These cards could provide information on identifying eiders and distinguishing among eider species as well as contact information for observations relevant to conservation.

3. The oil spill contingency plans for exploration and delineation wells drilled as a result of Lease Sale 186 should include measures and the capability to deploy at least 10 *Breco* buoys (or other similar devices, to be approved by the Service) to haze or scare seaducks from oiled

areas in the event of a marine spill. The spill plans should require that spill response personnel are knowledgeable of the location of available hazing devices and trained in their use.

4. To minimize disturbance of nesting, brood-rearing, and migrating spectacled and Steller's eiders with aircraft, the MMS should work with the Service to cooperatively develop project-specific aircraft flight route strategies for exploration and delineation drilling activities. Any decision regarding aircraft flight routes will comply with all appropriate Federal Aviation Administration (FAA) rules, regulations and policies. This recommendation does not apply to aviation activities conducted when eiders are not present (October 31- May 1).

Additional conservation recommendations may be proposed during subsequent incremental steps of this lease sale. In order for the Service to be kept informed of actions minimizing or avoiding adverse effects or benefitting listed species or their habitats, the Service requests notification of the implementation of any conservation recommendations.

REINITIATION NOTICE

This concludes formal consultation on the actions outlined in the MMS's letter received May 29, 2002. As provided in 50 CFR 402.16, reinitiation of formal consultation is required where discretionary Federal agency involvement or control over the action has been retained (or is authorized by law) and if: 1) the amount or extent of incidental take is exceeded; 2) new information reveals effects of the action agency that may affect listed species or critical habitat in a manner or to an extent not considered in this opinion; 3) the agency action is subsequently modified in a manner that causes an effect to listed or critical habitat not considered in this opinion; or 4) a new species is listed or critical habitat designated that may be affected by the action. In instances where the amount or extent of incidental take is exceeded, any operations causing such take must cease pending reinitiation.

Thank you for your concern for endangered species and for your cooperation in the development of this Biological Opinion. If you have any comments or require additional information, please contact Jonathan Priday at (907) 456-0499 with the Fairbanks Fish and Wildlife Field Office, Endangered Species Branch, Fairbanks, Alaska.

The total population of spectacled eiders is estimated at 375,000 (Larned and Tiplady 1999). From the early 1970s to the early 1990s, numbers of pairs on the Yukon-Kuskokwim Delta declined by 96 percent from 48,000 to 2,000, apparently stabilizing at that low level (Stehn et al. 1993, Petersen et al. 1999). On the North Slope, the mean numbers of breeding spectacled eiders estimated from aerial surveys between 1993 and 2001 ranged from a high of almost 9,300 in 1993 to a low of 5,800 birds in 1996 and back up to 7,370 birds in 2001 (Larned et al. 2001b).

Factors known or suspected to affect survival of spectacled eiders have been identified. However, the relative importance of these factors to the species' decline and to recovery are not known. The extent and causes of population declines or extirpations on the breeding grounds are difficult to assess because historical data are lacking for many locations. Several of the following factors are known to affect survival during the nesting season, but it is not clear whether they contributed to the decline of the spectacled eider population.

Lead ingestion from foraging habitat on breeding grounds in the Yukon-Kuskokwim Delta has been confirmed to cause mortality of eiders that ingested lead shot. The proportion of spectacled eiders on the Yukon-Kuskokwim Delta's lower Kashunuk River drainage that contained lead shot in their gizzards is high (11.6 percent, n=112) compared to other waterfowl in the lower 48 states from 1938-1954 (8.7 percent, n=5088) and from 1977-1979 (8.0 percent, n=12,880). The lead exposure rate in spectacled eiders (based on X-rays) is likely biased low (Flint et al. 1997), because lead is retained in the gizzard for only about 3 weeks (Elder 1954, Dieter and Finley 1978, Anderson and Havera 1986, Franson 1986, Anderson et al. 1987). Blood analyses of spectacled eiders indicate elevated levels of lead in 13 percent of pre-nesting females, 25.3 percent of females during hatch, and 35.8 percent during brood rearing. Nine of 43 spectacled eider broods (20.9 percent) contained 1 or more ducklings exposed to lead by 30 days after hatch (Flint et al. 1997). Spent lead shot in the lower Kashunuk River area and on Kigigak Island is causing additive mortality in spectacled eiders, that is, mortality over and above that caused by natural circumstances (Grand et al. in press). It is possible that exposure to lead occurs in small, localized hunting areas on the North Slope as well, however there are no site-specific data on lead contamination in this region.

Predation pressure on spectacled eider eggs, young, and adults may have increased in recent decades. Predators include Arctic foxes (*Alopex lagopus*), red foxes (*Vulpes fulva*), large gulls (*Larus* spp.), jaegers (*Stercorarius* spp.), and snowy owls (*Nyctea scandiaca*). Native elders on the North Slope believe that fox numbers have increased in recent decades as a result of reduced trapping. Population sizes of large gulls on the North Slope may have increased as a result of increased food supplies from anthropogenic wastes. Wastes made available from the commercial fishing industry in the Bering Sea and North Pacific, along with an increase in the garbage generated by coastal communities, have increased the year-round food supply for gulls.

Subsistence harvest of spectacled eider eggs and adults is another potential factor in the decline of the spectacled eider population. Alaska Natives have traditionally harvested eiders and their eggs in coastal villages during spring and fall. Although human populations on the Yukon-Kuskokwim Delta and in North Slope communities have grown substantially, changes in the numbers of hunters are unknown. In addition, improved technology for hunting has allowed greater efficiency, but the actual effects of these improvements on harvest levels are unknown.

There are other sources of take such as avicultural egg collecting (until 1991), research activity, and loss of habitat in growing communities and oilfields. Their overall impacts to the spectacled eider population is unknown.

Other potential factors that may affect spectacled eider survival have been suggested but not investigated. These include changes in the invertebrate community structure in their winter habitats, bioaccumulation of contaminants in the marine environment, human harvest for sport and subsistence outside their breeding grounds, disease, parasites, and accidental strikes and/or disturbance of benthic feeding areas by commercial fishing activity.

Steller's Eider

The Alaska-breeding population of Steller's eider was listed as threatened on June 11, 1997 (Federal Register 62(112): 31748- 31757). This action was based on a substantial decrease in the species' nesting range in Alaska, a reduction in the number of Steller's eiders nesting in Alaska, and the resulting increased vulnerability of the remaining breeding population to extirpation. Historically, Steller's eiders nested in Alaska in two general regions: 1) western Alaska, where the species has been nearly extirpated; and 2) the North Slope, where the species still occurs. In western Alaska, Steller's eiders occurred primarily in the coastal fringe of the Yukon-Kuskokwim Delta, where the species was common at some sites in the 1920s, was still present in the 1960s, but was not recorded as breeding from 1976-1994 (Kertell 1991, Flint and Herzog 1999). In 1994 and 1996-1998, 1-2 nests were found at either or both the Tutakoke River and Hock Slough study sites on the Yukon-Kuskokwim Delta (Flint and Herzog 1999).

On the North Slope, Steller's eiders historically occurred from Wainwright east, nearly to the United States-Canada border (Brooks 1915). The species may have abandoned the eastern North Slope in recent decades, but it still occurs at low densities from Wainwright to at least as far east as Prudhoe Bay. The majority of sightings in the last decade have occurred east of Point Lay, west of Nuiqsut on the Colville River, and within 90 km (56 miles) of the coast. Near Barrow, Steller's eiders still occur regularly, though they do not nest annually. In some years, up to several dozen pairs may breed in a few square kilometers.

Contemporary aerial breeding pair surveys conducted in late June indicate a population averaging about 1,000 birds from 1986-2000 (Mallek 2001). A separate set of aerial surveys,

ATTACHMENT 1

OCS Oil and Gas Lease Sale 186, Beaufort Sea
Consultation History

05/09/02 - MMS requests formal consultation from Service (Washington D.C. Office) for Lease Sale 186, and transmits Biological Evaluation.

05/22/02 - Service (FFWFO staff) and MMS meet to discuss initiating formal consultation Lease Sale 186.

05/23/02 - MMS transmits maps to Service comparing Beaufort Sea Lease Sales 144, 170 and proposed Lease Sale 186.

05/29/02 - The Service's Fairbanks Fish and Wildlife Office (FFWFO) receives MMS's Draft Lease Sale 186 EIS. Service begins reviewing it for completeness.

06/17/02 - Service Washington D.C. Office transmits acknowledgment of receipt of request for formal consultation and agrees to prepare draft Biological Opinion (BO).

07/10/02 - FFWFO receives MMS's completed/bound Draft Lease Sale 186 EIS and accompanying CD-ROM.

09/06/02 - Service and MMS discuss further information needs, potential delivery date for draft BO, and what the Service anticipate including as "Terms and Conditions."

09/10/02 - Service and MMS discuss uncertainties over quantifying number, location, and operational lifetime of potential exploratory and production drilling. Also discuss time lines and potential "Terms and Conditions."

09/11/02 - Service and MMS discuss BO. MMS stated their desire to get a BO by the end of the comment period on the EIS (9/20) so they could finalize the EIS. The Service explained their understanding of the time line and their desire to complete the BO on time.

09/17/02 - Service requests that MMS generate language that provides more refined estimates of total exploration/production activity that will result from Lease Sale 186 (include methodology for estimating number of wells and longevity of operation).

09/17/02 - MMS asks the Service to use their estimates of exploration/delineation activity in the EIS to generate incidental take. The Service explained to them that we can proceed but we would like them to send us something in writing explaining whether their exploration/production numbers in the EIS represent an average or maximum scenario.

09/18/02 - MMS and the Service meet to discuss due dates and scope of Lease Sale 186 BO. MMS stated that the exploration and development scenarios described in the Lease Sale 186 EIS were maximum estimates.

09/19/02 - Service tells MMS that the Service received MMS's request for consultation on May 29, 2002. Therefore, the 135-day clock for the Service issuing its BO terminates on October 10th not on September 21. The Service commits to providing MMS with a draft as soon as possible and prior to deadline.

09/19/02 - Service forwards MMS draft "Reasonable and Prudent Measures", "Terms and Conditions", and "Conservation Recommendations" sections from draft Lease Sale 186 BO.

09/27/02 - Service transmits draft BO to MMS.

10/02/02 - MMS and Service discuss MMS's comments on the Service's draft Lease Sale 186 BO. The Service agrees to consider MMS's comment and get them a revised draft BO by Monday at 5:00 p.m..

10/07/02 - Service transmits revised draft BO via email to MMS.

10/10/02 - MMS transmits comments on revised draft BO via email. MMS states that if their changes are acceptable to the Service, another meeting to further discuss the draft BO is not necessary.

10/17/02 - Service makes changes to draft Biological Opinion and transmits it back to MMS via email.

10/18/02 - MMS transmits comments on revised draft BO via email.

10/18/02 - Service and MMS discuss MMS's comments and agree to language for final BO.

United States Department of the Interior

MINERALS MANAGEMENT SERVICE
Washington, DC 20240

MAY 9 2002

Memorandum

To: Assistant Director for Endangered Species
U.S. Fish and Wildlife Service

From: Thomas A. Readinger
for Associate Director for Offshore Minerals Management

Subject: Endangered Species Act Section 7, Consultation Request for the Proposed Beaufort Sea Lease Sales from 2003 Through 2007

The Minerals Management Service has completed the draft Environmental Impact Statement for the proposed multiple oil and gas lease sales in the Beaufort Sea for the time period 2003-2007. The proposed Beaufort Sea oil and gas Lease Sales 186, 195, and 202 are planned for September 2003, 2005, and 2007 respectively.

Under section 7(a)(2) of the ESA, the MMS requests formal consultation with the U. S. Fish and Wildlife Service on leasing and exploration activities associated with these proposed sales. The consultation should address all aspects of activities associated with oil and gas leasing and exploration. We understand that when the FWS issues a biological opinion for the Beaufort Sea proposed oil and gas lease sales, the FWS does not relinquish the opportunity to reconsider and modify that opinion for future proposed sales. Therefore, the MMS will prepare an Environmental Assessment for each subsequent proposed sale covered by this EIS and send those EAs to FWS for review. We also ask that the FWS biological opinion supercede all existing biological opinions for leasing and exploration activities in the Beaufort Sea.

To facilitate completion of this consultation, we are sending copies of this memorandum and attachments to FWS Region 7 Office in Anchorage, Alaska, and the Northern Alaska Ecological Services Office in Fairbanks, Alaska. The draft EIS contains information on the anticipated composition, procedures, execution, and effects of the proposed Beaufort Sea oil and gas lease sales and exploration activities. The draft EIS, which serves as our biological evaluation for the proposed action, satisfies the information requirements specified in 50 CFR 402.12 and 402.14. We request that the biological opinion be prepared in as timely a manner as possible to allow the MMS to include it in the final EIS in January 2003 and to ensure consideration by the Secretary of the Interior during the decisionmaking process for Lease Sale 186.

If you consider recommending measures to minimize impacts to threatened and endangered species or determine a jeopardy situation may exist for all or any part of the proposed action, we ask that you notify us as early as possible, according to 50 CFR 402. 14(g)(5), to allow the MMS and FWS staff time to jointly discuss the findings. We believe that such discussions will facilitate the consultation and ensure effective protection of listed species. These discussions can also ensure that any proposed alternatives are within our authority to control and implement, and are feasible, appropriate, and effective.

If you have any questions on this consultation or require additional information, please contact Ms. Judy Wilson, Minerals Management Service, Mail Stop 4042, 381 Elden Street, Herndon, Virginia 20170-4817 (commercial and FTS telephone: (703) 787-1075), or Mr. Fred King, Minerals Management Service, Alaska OCS Region, Mail Stop 8303, 949 East 36th Avenue, Suite 300, Anchorage, Alaska 99503-4363 (commercial and FTS telephone: (907) 271-6696).

MINERALS MANAGEMENT SERVICE
Washington, DC 20240

MAY 9 2002

Mr. Donald Knowles
Director, Office of Protected Resources
National Oceanic and Atmospheric
Administration Fisheries
1315 East-West Highway, SSMC3
Silver Spring, Maryland 20910

Dear Mr. Knowles:

The Minerals Management Service has completed a draft Environmental Impact Statement for the proposed multiple oil and gas lease sales in the Beaufort Sea for the time period 2003-2007. This is the first multiple-sale EIS the MMS has prepared for the Beaufort Sea Planning Area. The proposed Beaufort Sea oil and gas Lease Sales 186, 195, and 202 are planned for September 2003, 2005, and 2007 respectively.

On March 10, 2000, under section 7(a)(2) of the Endangered Species Act and 50 CFR 402.16, the MMS requested the National Oceanic Atmospheric Administration Fisheries to reinitiate consultation on the November 23, 1988, biological opinion concerning leasing and exploration activities in the Beaufort Sea. The NOAA Fisheries issued a new non-jeopardy Beaufort Sea biological opinion on May 25, 2001. The biological opinion addressed the incremental step of leasing and exploration in the Alaskan Beaufort Sea Outer Continental Shelf Planning Area. The MMS has determined there is no new information revealing effects of the proposed activities expected as a result of multiple sales that may affect the bowhead whale in a manner or to an extent not previously considered in the May 2001 biological opinion. Nor have the proposed activities been modified to cause an effect to bowhead whales not considered in the May 2001 biological opinion.

Under section 7(a)(2) of the ESA, we request that you uphold the biological opinion issued in May 2001 concerning Beaufort Sea oil and gas leasing and exploration activities for proposed Lease Sales 186, 195, and 202. We request that the results of this consultation be prepared in as timely a manner as possible to allow MMS to include it in the final EIS in January 2003, and to ensure consideration by the Secretary of the Interior during the decisionmaking for Lease Sale 186. We also ask that you affirm that the May 2001 biological opinion supercedes all existing biological opinions for leasing and associated exploration activities the Beaufort Sea Planning Area. We understand that when NOAA Fisheries issues a biological opinion for the proposed oil and gas lease sales in the Beaufort Sea Planning Area, NOAA Fisheries does not relinquish the opportunity to reconsider and modify that opinion for future proposed sales. Therefore, the MMS will prepare an Environmental Assessment for each subsequent proposed sale covered by this draft EIS and send those EAs to NOAA Fisheries for review.

We submit for your review the draft EIS for Beaufort Sea Lease Sales 186, 195, and 202 in hard copy and CD format to assist you in completing this consultation. The draft EIS contains information on the anticipated composition, procedures, execution, and effects of the proposed Beaufort Sea oil and gas lease sales and associated exploration. The draft EIS, which serves as our biological evaluation for the proposed action, satisfies the information requirements specified in 50 CFR 402.12 and 402.14. We are glad to provide any additional information that you may find necessary for your deliberations. To facilitate completion of this consultation, we are sending a copy of this letter and enclosures to the NOAA Fisheries Alaska Regional Office in Juneau, Alaska, and the Anchorage Field Office.

If you have any questions on this consultation, please address them to Ms. Judy Wilson, Minerals Management Service, Mail Stop 4042, 381 Elden Street, Herndon, Virginia 20170-4817 (commercial and FTS telephone: (703) 787-1075), or Mr. Fred King, Minerals Management Service, Alaska OCS Region, Mail Stop 8303, 949 East 36th Avenue, Suite 300, Anchorage, Alaska 99508-4363 (commercial and FTS telephone: (907) 271-6696).

Sincerely,

Michael Hunt

July 23, 2002

Thomas A. Readinger
Associate Director for Offshore Minerals Management
Minerals Management Service
Washington, D.C. 20240

Dear Mr. Readinger:

Thank you for your letter concerning the need for consultation under section 7 (a)(2) of the Endangered Species Act of 1973 (ESA), as amended, for the proposed multiple oil and gas lease sales in the Beaufort Sea for the time period 2003-2007. Your letter has been forwarded to my attention. In your letter, you request that the National Marine Fisheries Service (NMFS) uphold the May 25, 2001, biological opinion for oil and gas leasing and exploration activities in the Beaufort Sea by determining that the opinion satisfies the consultation requirements of the ESA for the following proposed sales; Sales 186, 195, and 202. These sales would occur in the years 2003, 2005, and 2007, respectively. In June, 2002, the Minerals Management Service prepared a draft Environmental Impact Statement (EIS) for these three sales. A supplemental EIS or Environmental Assessment will be prepared for Sales 195 and 202 in order to determine whether or not the information and analysis in the 2002 EIS remains valid for those future dates.

NOAA Fisheries has reviewed the EIS and other information relative to the effects of the proposed sales on ESA species and/or critical habitats under our jurisdiction. We find the May 2001 opinion addresses these sales, in terms of the listed species and habitats present, the legal status of these species under the ESA having been unchanged, the anticipated actions associated with these sales being consistent with those actions considered in the opinion, and the sale area being consistent with that previously assessed. We also affirm that the May 2002 opinion supercedes all existing biological opinions for leasing and associated exploration activities in the Beaufort Sea Planning Area. In view of this finding, NOAA Fisheries believes the section 7 consultation requirements of the ESA have now been met for Sale 186. We have not applied this conclusion to Sales 195 and 202 at this time however, as the logic which MMS has used in determining the need for supplemental analysis under NEPA for these sales would also extend to ESA consultation. The applicability of the May 2002 opinion will be reconsidered prior to these subsequent sales.

Please direct any questions to Mr. Brad Smith at the Anchorage, Alaska, office, NMFS, at (907) 271-5006.

Sincerely,

P. Michael Payne
Assistant Administrator
for Protected Resources
Alaska Region

cc: Brad Smith, AKR, NMFS

APPENDIX D

APPLICABLE FEDERAL LAWS
REGULATORY RESPONSIBILITIES,
AND
EXECUTIVE ORDERS

APPLICABLE FEDERAL LAWS, REGULATORY RESPONSIBILITIES, AND EXECUTIVE ORDERS

APPLICABLE FEDERAL LAWS, REGULATORY RESPONSIBILITIES, AND EXECUTIVE ORDERS

This appendix briefly explains or summarizes only those portions of Federal public laws enacted by Congress (see the list of legal mandates in Section I.B of this EIS) and other applicable Federal regulatory responsibilities, executive orders, and stipulations (mitigating measures) as they relate directly or indirectly to Minerals Management Service's (MMS's) management of mineral leasing, exploration, and development and production activities on leases located in the submerged lands of the Outer Continental Shelf (OCS). Additionally, this section includes responsibilities and jurisdictions of other Federal Agencies and departments involved in the regulatory process of oil and gas lease sales and operations on the OCS. This is not intended to be a comprehensive summary or explanation of all the laws associated with proposed leasing, exploration, and development and production activities that might significantly affect the OCS. References, explanations, or summaries are given only to acquaint the reader with the law and are not meant as legal interpretations. Readers always should consult the entire text of the laws for updates and additional requirements and information.

D.1. Federal Laws and Regulatory Responsibilities

D.1.a. The Outer Continental Shelf Lands Act

A jurisdictional dispute concerning the ownership of coastal submerged lands arose as new technology became available for developing offshore oil resources in increasingly deeper waters. This dispute was resolved in 1953 by two congressional statutes that clarified Federal and State rights and responsibilities for the "continental shelf" (the submerged lands extending from the coastline to the edge of the continental slope). The first statute, the Submerged Lands Act of 1953 (43 U.S.C. § 1331 et seq.), affirmed the coastal states' assertion of ownership of the submerged lands and resources within a 3-mile belt seaward of the line of low tide. The second statute, the OCS Lands Act of 1953, as amended (43 U.S.C. § 1331 et seq.), established that the submerged lands and resources of the OCS or beyond 3 miles, "appertained to the United States and [were] subject to its jurisdiction, control, and power of disposition." The OCS Lands Act authorizes the Secretary of the U.S. Department of the Interior (USDOI) to issue mineral leases and grant rights-of-way and to prescribe regulations governing oil and gas activities on OCS lands.

The OCS Lands Act defines the OCS as:

> ...all submerged lands lying seaward and outside of the areas lands beneath navigable waters as defined in section 2 of the Submerged Lands Act and of which the subsoil and seabed appertain to the United States and are subject to its jurisdiction and control.

The pertinent provision of the Submerged Lands Act defines "navigable waters" as:

> ...all lands permanently or periodically covered by tidal waters up to but not above the line of mean high tide and seaward to a line three geographical miles distant from the coast line of each such State and to the boundary line of each such State where in any case such boundary as it existed at the time such State became a member of the Union, or as heretofore approved by Congress, extends seaward (or into the Gulf of Mexico) beyond three geographical miles....

Under the OCS Lands Act, the Department of the Interior is required to:
- make Federal OCS resources available to meet the Nation's energy needs;
- conduct, develop, and manage the orderly leasing, exploration, development, and production of mineral resources on the Federal OCS;
- balance orderly energy resource development while ensuring the protection of the human, marine, and coastal environments;
- ensure that the public receives a fair and equitable return for Federal OCS resources; and
- ensure that free-enterprise market competition is preserved and maintained.

The Secretary of the Interior has delegated the responsibility of managing and regulating the development of OCS oil and gas resources in accordance with the provisions of the OCS Lands Act to the MMS.

The MMS leasing regulations are presented in Chapter 30, Code of Federal Regulations (CFR) part 256. The MMS operating regulations governing exploration, development, and production on OCS leases are presented in 30 CFR parts 250 and 270.

The OCS Lands Act extends the authority of the Secretary of the Army, through the Corps of Engineers, to the OCS to prevent obstruction to navigation in U.S. navigable waters.

The OCS Lands Act grants authority to the U.S. Coast Guard to promulgate and enforce regulations covering lighting and warning devices, safety equipment, and other safety-related matters pertaining to life and property on fixed OCS platforms and drilling vessels.

In accordance with the OCS Lands Act (43 U.S.C. § 1354) and the Export Administration Act of 1969 (50 App. U.S.C. 2405(d)), oil that is produced on the U.S. OCS must go to a U.S. port.

D.1.b. The National Environmental Policy Act of 1969 and the Council on Environmental Quality

The National Environmental Policy Act of 1969 (NEPA), as amended (42 U.S.C. § 4321 et seq.), is the foundation of environmental policymaking in the U.S. Recognizing the profound impact of human activity on the interrelations of all components of the natural environment, the Congress declares in NEPA that it is the continuing policy of the Federal Government, in cooperation with State and local governments and other concerned public and private organizations, to use all practicable means and measures, including financial and technical assistance, in a manner calculated to foster and promote the general welfare; to create and maintain conditions under which humans and nature can exist in productive harmony; and fulfill the social, economic, and other requirements of present and future generations of Americans. The Congress authorizes and directs that, to the fullest extent possible, the policies, regulations, and public laws of the U.S. shall be interpreted and administered in accordance with the policies set forth in NEPA. The NEPA process is intended to help Federal officials make decisions based on an understanding of environmental consequences and take actions that protect, restore, and enhance the environment.

The NEPA established two primary mechanisms for this purpose:
1. The Council on Environmental Quality (CEQ) was established to advise Federal Agencies on the environmental decisionmaking process and to oversee and coordinate the development of Federal environmental policy.
2. Federal Agencies must include an environmental review process early in the planning for proposed actions.

Congress first established the CEQ as part of the NEPA. Additional responsibilities were provided by the Environmental Quality Improvement Act of 1970. The CEQ established uniform procedures by issuing regulations (40 CFR, parts 1500 through 1508) to implement the procedural provisions of NEPA. These regulations include procedures to be used by Federal Agencies for the environmental review process. The regulations provide for the use of the NEPA process to identify and assess reasonable alternatives to proposed Federal actions that avoid or minimize adverse effects of these actions on the quality of the human environment.

The NEPA requires all Federal Agencies to use a systematic, interdisciplinary approach to protect the human environment. Such an approach ensures the integrated use of natural and social sciences in any planning and decisionmaking that may have an impact on the environment. The NEPA also requires the preparation of a detailed environmental impact statement (EIS) on any major Federal action that may have a significant impact on the environment. The EIS must address any adverse environmental effects that cannot be avoided or mitigated, alternatives to the proposed action, the relationship between short-term resources and long-term productivity, and irreversible and irretrievable commitments of resources. Environmental assessments (EA's) are prepared to determine if significant impacts may occur. If an EA finds that significant impacts may occur, NEPA requires the preparation of an EIS. The briefest form of NEPA review is the categorical exclusion review, which verifies that neither an EA nor an EIS is needed before making a decision on the activity being considered for approval.

For compliance with the NEPA, see 40 CFR, parts 1500 through 1508.

D.1.c. The Clean Air Act of 1970 and the Clean Air Act Amendments of 1990

The Clean Air Act of 1970 (42 U.S.C. § 7401 et seq.), authorizes the U.S. Environmental Protection Agency (USEPA) to establish National (primary or secondary) standards within air-quality-control regions of each state in addition to National emission standards for hazardous air pollutants (National Ambient Air Quality Standards [NAAQS]). The Act requires Federal departments or agencies that have jurisdiction over any property or facility or that are engaged in any activity resulting from the discharge of air pollutants to comply with all Federal, State, interstate, and local requirements in the control and abatement of air pollution. Section 5(a)(8) of the OCS Lands Act requires MMS, through the Secretary of the Interior, to ensure that OCS regulations incorporate and comply with NAAQS.

The 1990 Clean Air Act Amendments (CAA) delineate jurisdiction of air quality between the USEPA and the U.S. Department of the Interior (USDOI), MMS and affect the attainment and maintenance of NAAQS (Title I), motor vehicles and fuel reformulation (Title II), hazardous air pollutants (Title III), acid deposition (Title IV), facility operating permits (Title V), stratospheric ozone protection (Title VI), and enforcement (Title VII).

Section 328 of the CAA transfers authority for air quality on the OCS to the USEPA. Under the CAA, the Secretary of the Interior is required to consult with the USEPA "to assure coordination of air pollution control regulations for OCS emissions and emissions in adjacent onshore areas." On September 4, 1992, the USEPA promulgated requirements (40 CFR, part 55) to control air pollution from OCS sources to attain and maintain Federal and State air-quality standards and to comply with CAA provisions for the Prevention of Significant Deterioration. The promulgated regulations require OCS sources to comply with applicable onshore air-quality rules in the corresponding onshore area.

On November 30, 1993, the USEPA instituted final rules for determining general conformity of Federal actions with Federal and State air-quality implementation plans. Section 176(c) of the CAA, the General Conformity Rule, requires Federal Agencies to ensure that actions undertaken in nonattainment or maintenance areas are consistent with the applicable implementation plan. A Federal Agency must make a determination that a Federal action conforms to the applicable implementation plan before the Federal action is taken.

To comply with the CAA, the MMS established regulations to address air quality concerning OCS operations. These regulations are found under 30 CFR 250.302, 250.303, and 250.304. The regulated pollutants include carbon monoxide, particulates, sulfur dioxide, nitrogen oxides, and volatile organic compounds (as a precursor to ozone). In areas where hydrogen sulfide may be present, OCS operations are regulated by 30 CFR 250.417. The MMS regulations allow for the collection of information about potential sources of pollution for the purpose of determining whether the projected emissions of air pollutants from a facility could result in ambient onshore air-pollutant concentrations above maximum levels provided in the regulations. These regulations also stipulate appropriate emissions controls considered necessary to prevent accidents and air-quality deterioration.

D.1.d. The Federal Water Pollution Control Act and Clean Water Act

The Federal Water Pollution Control Act (FWPCA) of 1972, as amended (33 U.S.C. § 251 et seq.), established water-pollution-control activities to restore and maintain the chemical, physical, and biological integrity of the Nation's waters. The Clean Water Act (CWA) of 1977 (91 Stat. 1566) amended the FWPCA. Most activities are administered by the USEPA.

Title III of the CWA requires the USEPA to establish national effluent limitation standards for existing point sources of wastewater discharges that reflect the application of the best practical control technology currently available. These standards apply to existing OCS exploratory drillships, semisubmersible vessels, and jackup rigs used in exploration activities. The CWA also requires the USEPA to establish regulations for effluent limitations for categories and classes of point sources that require the application of "best available control technology economically achievable."

Section 311 of the CWA (33 U.S.C. § 1321), as amended, prohibits the discharge of oil or hazardous substances into the navigable waters of the U.S. that may affect natural resources, except under limited circumstances, and establishes civil penalty liability and enforcement procedures to be administered by the Coast Guard.

Title IV of the CWA establishes requirements for Federal permits and licenses to conduct an activity (including construction or operation of facilities) that may result in any discharges into navigable waters. Section 402 of the CWA (33 U.S.C. § 1342) gives the USEPA the authority to issue National Pollutant Discharge Elimination System (NPDES) permits for discharges of any pollutant from a point source into navigable waters. The NPDES permits are issued in compliance with USEPA's guidelines for determining the degradation of marine waters, and they apply to all sources of wastewater discharges from exploratory vessels and production platforms operating on the OCS.

Section 404 of the CWA (33 U.S.C. § 1344) authorizes issuance of permits, under certain criteria, for discharge of dredged or fill material into navigable waters at specified disposal sites. The Secretary of the Army, acting through the Corps of Engineers, has the authority to administer Section 404. Permits may be issued only after a determination is made that the activities involving discharges of dredged or fill material are similar in nature, will cause only minimal adverse environmental effects when performed separately, and will have only minimal cumulative adverse effects on the environment.

Pursuant to the 1984 Memorandum of Understanding between the USEPA and the USDOI concerning the coordination of NPDES permit issuance with the OCS oil and gas lease program, the MMS Alaska OCS Region and the USEPA Region 10 entered into a Cooperating Agency Agreement to prepare EIS's for oil and gas exploration and development and production activities on the Alaskan OCS. Section 402 of the CWA authorizes the USEPA to issue NPDES permits to regulate discharges to waters of the U.S., including the territorial seas, contiguous zone, and oceans. The NPDES permits for OCS oil and gas facilities many contain effluent limitations developed pursuant to sections of the CWA, including sections 301, 302, 306, 307, and 403. With the offshore subcategory under the CWA, the USEPA may have NEPA responsibilities for permits issued to new sources (Section 306 of the CWA), that overlap with those of the MMS. The USEPA's primary role in the Cooperating Agency Agreement is to provide expertise in those fields specifically under its mandate.

In conjunction with the issuance of an NPDES permit, the USEPA is responsible for publishing an Ocean Discharge Criteria Evaluation (ODCE) that evaluates the impacts of waste discharges proposed for oil and gas projects. The purpose of the ODCE is to demonstrate whether or not a particular discharge will cause unreasonable degradation to the marine environment.

For multiple-use conflicts, see the USEPA listing of ocean-dumping sites found under 40 CFR part 228.

The MMS pollution prevention and control regulations are found under 30 CFR 250.300.

D.1.e. The Coastal Zone Management Act and the Coastal Zone Reauthorization Amendments

Congress passed the Coastal Zone Management Act (CZMA) of 1972, as amended (16 U.S.C. § 1451 et seq.) and created the Coastal Zone Management Program to improve the management of the Nation's coastal areas. Both the Coastal Zone Reauthorization Amendments of 1990 (P.L. No. 101-508), enacted November 5, 1990, and the Coastal Zone Protection Act of 1996 (P.L. No. 104-150), enacted June 3, 1996, amended and reauthorized the CZMA. The Program, a voluntary partnership between the Federal Government and the coastal states and territories, is administered at the Federal level by the National Oceanic and Atmospheric Administration (NOAA) within the U.S. Department of Commerce (USDOC). The Program's goal is to reduce conflict between environmental and economic interest in the coastal area through the use of federally approved coastal management programs (CMP's). Each state's CZM program sets forth objectives, policies, and standards regarding public and private use of land and water resources in that state's coastal zone.

The CZMA allows a coastal state or territory with a federally approved CMP to review Federal activities for Federal consistency. Consistency applies whenever a Federal activity initiates a series of events where coastal effects are reasonably foreseeable (see H.R. Rep. No. 1012, 96th Cong., 2d Sess. 4382). The CZMA requirement that all Federal activity, including OCS oil and lease sales, regardless of location (in or outside the coastal zone) that is reasonably likely to affect any land or water use or natural resource of the coastal zone be consistent with the enforceable policies of a state's/territory's CMP. Section 307 of the CZMA (16 U.S.C. § 1456) contains the following Federal consistency provisions that impose certain requirements on Federal Agencies to comply with enforceable policies detailed in the federally approved CMP's:

> Section 307(c)(1) requires that Federal Agencies must conduct their activities, regardless of location, if coastal effects are reasonably foreseeable, that affects any land or water use or natural resources of the coastal zone in a manner that is fully consistent to the maximum extent practicable with enforceable policies of the affected state's coastal zone management (CZM) program. This section applies to OCS lease sales. On May 3, 1995, the MMS Regional Director, Alaska OCS Region, and the Director, Alaska Division of Governmental Coordination signed a Memorandum of Understanding Between State of Alaska Division of Governmental Coordination and USDOI, MMS Alaska OCS Region. This document facilitates and coordinates both agencies' efforts with respect to consistency determination procedures prior to MMS Alaska OCS Region's oil and gas lease sales.
>
> Section 307(c)(3)(A) requires that any Federal licenses/permits affecting any land or water use or natural resources of the coastal zone be consistent with enforceable policies of the state's CMP. This section applies to geological and geophysical permits. Additionally, this section prohibits the Federal Agency from issuing the license/permit until the affected state(s) has concurred with or presumed to concur with the applicant's consistency certification or until the Secretary of Commerce has overridden the state's consistency objection to the licensed/permitted activity.
>
> Section 307(e)(3)(B) requires that activities affecting any land or water use or natural resources of the coastal zone, described in detail in OCS exploration or development and production plans, be consistent with enforceable policies of the state's CMP. The MMS is prohibited from approving an OCS plan until the affected state(s) has concurred with or is presumed to concur with the applicant's consistency certification, or until the Secretary of Commerce has overridden the state's consistency objection. On August 7, 1980, a Memorandum of Understanding Between Division of Policy and Development and Planning and U.S. Geological Survey was signed between the State of Alaska and MMS (formerly USGS). This document establishes procedures for coordinating plans and programs for consistency review and includes procedures for approvals of

exploration plans, development and production plans, and other licenses and permits for OCS activities.

On December 8, 2000, NOAA revised the regulations that implement the Federal consistency provisions of the CZMA with federally approved CMP's. These regulations are found under 15 CFR § 930.

The MMS regulations for CZMA consideration affecting OCS lease sales are found under 30 CFR 256.20. The MMS regulations for CZMA consideration affecting OCS operations and/or permit activities are found under 30 CFR 250.203, 250.204, 250.414, and 250.417.

D.1.f. The Energy Policy and Conservation Act

The Energy Policy and Conservation Act of 1975 (42 U.S.C. § 6213 et seq.) prohibits joint bidding by major oil and gas producers. Bidders submitting bids on OCS leases are subject to the provisions of 18 U.S.C. 1860, prohibiting unlawful combination or intimidation of bidders (30 CFR 256.46(f)).

The MMS authority and regulations for compliance with the Energy Policy and Conservation Act of 1975 are found under 30 CFR 256.4, 256.41, and 256.44.

D.1.g. The Marine Mammal Protection Act

The Marine Mammal Protection Act (MMPA) of 1972, as amended (16 U.S.C. § 1361 et seq.) was enacted to ensure that marine mammals are maintained at or, in some cases, restored to healthy population levels. Jurisdiction and regulatory responsibility for the conservation and protection of these marine mammals under the MMPA is split between two Federal Agencies. The Secretary of the Interior is responsible for walruses, polar bears, sea otters, manatees, and dugongs and has delegated this responsibility to the Fish and Wildlife Service (FWS). The Secretary of Commerce is responsible for the protection of all other marine mammals (cetaceans and pinnipeds [except walruses]) and has delegated the authority for implementing the MMPA to the National Marine Fisheries Services (NMFS).

The Marine Mammal Commission is responsible for reviewing and advising Federal Agencies on the protection and conservation of marine mammals. The commission has a Committee of Scientific Advisors that provides advice on actions needed to fulfill the purposes of the MMPA. The commission is authorized to make recommendations on the prohibition of taking and importing marine mammals and marine mammal products, except as expressly provided for by an international treaty, convention, or agreement to which the U.S. is a party.

The MMPA established a moratorium on the taking or importing of marine mammals in waters under U.S. jurisdiction except during certain activities that are regulated and permitted. Such activities include scientific research, public display, and the incidental take of marine mammals in the course of commercial-fishing operations. The MMPA defines "take" to mean "hunt, capture, or kill or attempt to harass, hunt, capture, or kill any marine mammal." "Harass" is defined as any act of pursuit, torment, or annoyance that has the potential to injure a marine mammal or marine mammal stock in the wild; or has the potential to disturb a marine mammal or marine mammal stock in the wild by causing disruption of behavioral patterns including, but not limited to, migrating, breathing, nursing, breeding, feeding, or sheltering.

The moratorium may be waived when the affected species or population stock is within its optimum sustainable population range and would not be disadvantaged by the authorized taking (for example, be reduced below its maximum net productivity level), which is the lower limit of the optimum sustainable population range. On request, the Secretary (of either the USDOI or the USDOC, depending on jurisdiction) can authorize the unintentional taking of small numbers of marine mammals incidental to activities other than commercial fishing (for example, offshore oil and gas exploration and development) when, after notice and opportunity for public comment, the Secretary finds that the total of such taking during the 5-year (or less) period would have a negligible impact on the affected species. Also, the Secretary will withdraw, or suspend for a specified time, permission to take marine mammals incidental to oil and gas production, and other activities if the applicable regulations concerning the methods of taking, monitoring, or reporting are not being complied with, or the taking is having, or may be having, more than a negligible impact on the affected species or stock.

In 1994, a new subparagraph (D) was added to Section 101(a)(5) of the MMPA to simplify the process of obtaining "small take" exemptions when unintentional taking is by incidental harassment only. Specifically, the incidental take of small numbers of marine mammals by harassment can now be authorized for periods of up to 1 year without the rulemaking as required by Section 101(a)(5)(A), which remains in effect for other authorized types of incidental taking.

To ensure that activities on the OCS adhere to MMPA regulations, the MMS must actively seek information concerning impacts of OCS activities on local species of marine mammals. The MMPA provides exemptions to taking of certain marine mammals by Alaskan Natives under certain conditions. The MMS coordinates with the FWS and NMFS to ensure that the MMS and offshore operators comply with the MMPA and to identify mitigation and monitoring requirements for permits or approvals for OCS activities, such as seismic surveys and platform removals.

D.1.h. The Migratory Bird Treaty Act

The Migratory Bird Treaty Act of 1918 (MBTA), as amended (16 U.S.C. § 703-712), is the domestic law that affirms, or implements, the United States' commitment to four international conventions with Canada, Japan, Mexico, and Russia for the protection of shared migratory bird resources.

The MBTA governs the taking, killing, possession, transportation, and importation of migratory birds, their eggs, parts and nests. The take of all migratory birds is governed by the MBTA's regulation of taking migratory birds for educational, scientific, and recreational purposes and requiring harvest to be limited to levels that prevent overutilization. Section 704 of the MBTA states that the Secretary of the Interior is authorized and directed to determine if, and by what means, the take of migratory birds should be allowed and to adopt suitable regulations permitting and governing take. The Secretary in adopting regulations is to consider such factors as distribution and abundance to ensure that take is compatible with the protection of the species.

The provisions of the MBTA apply equally to Federal and non-Federal entities and prohibits the take, possession, import, export, transport, selling, purchase, barter, or offering for sale, purchase or barter, any migratory bird, their eggs, parts, and nests, except as authorized under a valid permit (50 CFR 21.11). Certain exceptions apply to employees of the Department of the Interior to enforce the MBTA and to employees of Federal agencies, State game departments, municipal game farms or parks, and public museums, public zoological parks, accredited institutional members of the American Association of Zoological Parks and Aquariums (now called the American Zoo and Aquarium Association) and public scientific or educational institutions.

D.1.i. The International Convention of the Prevention of Pollution from Ships and Marine Plastics Pollution Research and Control Act

In 1978, the International Convention of the Prevention of Pollution from Ships (MARPOL) was updated to include five annexes on ocean dumping. By signing onto MARPOL, countries agree to enforce Annexes I and II (oil and noxious liquid substances) of the treaty. Annexes III (hazardous substances), IV (sewage), and V (plastics) are optional. The U.S. is signatory to two of the optional MARPOL Annexes (III and V). Annex V is of particular importance to the maritime community (for example, shippers, oil-platform personnel, fishers, and recreational boaters) because it prohibits the disposal of plastics at sea and regulates the disposal of other types of garbage at sea. The Coast Guard is the enforcement agency for MARPOL Annex V within the U.S. Exclusive Economic Zone (EEZ) (within 200 miles of the U.S. shoreline).

The Marine Plastic Pollution Research and Control Act (MPPRCA) of 1988 (33 U.S.C. § 1901 et seq.) is the Federal law implementing MARPOL Annex V in all U.S. waters. Under the MPPRCA, it is illegal to throw plastic trash off any vessel within the EEZ. It also is illegal to throw any other garbage (for example, orange peels, paper plates, glass jars, and monofilament fishing line) overboard while navigating in inland waters or within 3 miles offshore. The greater the distance from shore, the fewer restrictions apply to nonplastic garbage. However, dumping plastics overboard in any waters anywhere is illegal at anytime. Fixed and floating platforms, drilling rigs, manned productions platforms, and support vessels operating under a Federal oil and gas lease are required to develop waste management plans and to post placards reflecting discharge limitations and restrictions. Garbage must be brought ashore and properly disposed of in a trash can, dumpster, or recycling container. Docks and marinas are required to provide facilities to handle normal amounts of garbage from their paying customers. Violations of MARPOL or MPPRCA may result in a fine of up to $50,000 for each incident. If criminal intent can be proven, an individual may be fined up to $250,000 and/or imprisoned up to 6 years. If an organization is responsible, it may be fined up to $500,000 and/or receive 6 years of imprisonment.

D.1.j. The Marine Protection, Research, and Sanctuaries Act

The Marine Protection, Research, and Sanctuaries Act (MPRSA) of 1972, as amended (33 U.S.C. § 1401-1445 and 16 U.S.C. § 1431-1445) regulates ocean dumping of waste, provides for a research program on ocean dumping, and provides for the designation and regulation of marine sanctuaries. Also known as the Ocean Dumping Act, the MPRSA regulates the ocean dumping of all material beyond the territorial limit (3 miles from shore) and prevents or strictly limits dumping material that "would adversely affect human health, welfare, or amenities, or the marine environment, ecological systems, or economic potentialities." Material includes, but is not limited to, dredged material; solid waste; incinerator residue; garbage; sewage; sewage sludge; munitions; chemical and biological warfare agents; radioactive materials; chemicals; biological and laboratory waste; wrecked or discarded equipment; rocks; sand; excavation debris; and industrial, municipal, agricultural, and other waste. The term does not include sewage from vessels or oil, unless the oil is transported via a vessel or aircraft for the purpose of dumping. Disposal by means of a pipe, regardless of how far at sea the discharge occurs, is regulated by the CWA through the NPDES permit process. Permits under Section 103 of this Act for dumping dredged material into ocean waters are issued by the Corps of Engineers.

Title III of the MPRSA, later called the National Marine Sanctuaries Act, charged the Secretary of Commerce to identify, designate, and manage marine sites based on conservation and ecological, recreational, historical, aesthetic, scientific, or educational value within significant national ocean and Great Lakes waters. Twelve national marine sanctuaries, representing a wide variety of ocean environments, have been designated. The National Marine Sanctuary Program is administered by USDOC, NOAA.

The regulations regarding designation and management of marine sanctuaries are found under 15 CFR § 922.

D.1.k. The National Fishing Enhancement Act

The National Fishing Enhancement Act of 1984 (33 U.S.C. § 2101 et seq.), also known as the Artificial Reef Act, established broad artificial reef development standards and a national policy to encourage the development of artificial reefs that will enhance fishery resources and commercial and recreational fishing. The national plan identifies oil and gas structures as acceptable material of opportunity for artificial reef development. The MMS adopted a rigs-to-reefs policy in 1985 in response to this Act and to broaden interest in the use of petroleum platform as artificial reefs.

D.1.l. The Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson-Stevens Fishery Conservation and Management Act (FCMA) of 1976 (16 U.S.C. § 1801 et seq.) established and delineated an area from the states' seaward boundary to approximately 200 nautical miles out as a fisheries conservation zone for the U.S. and its possessions. The Act created eight regional Fishery Management Councils (FMC's) and mandated a continuing planning program for marine fisheries management by the FMC's. The Act, as amended, requires that a Fishery Management Plan (FMP) (50 CFR 600), based on the best available scientific and economic data, be prepared for each commercial species (or related group of species) of fish in need of conservation and management within each respective region.

The FCMA was reauthorized by Congress through passage of the Sustainable Fisheries Act of 1996. This reauthorization implements a number of reforms and changes. One change required the NMFS to designate and conserve Essential Fish Habitat (EFH) for those species managed under an existing FMP. By designating EFH's, Congress hoped to minimize, to the extent practicable, any adverse effects on habitat caused by fishing or nonfishing activities and to identify other actions to encourage the conservation and enhancement of such habitat. The phrase "essential fish habitat," as defined in the Sustainable Fisheries Act of 1996, encompasses "those waters and substrate necessary to fishes for spawning, breeding, feeding, or growth to maturity." As a result of this change, Federal Agencies must consult with NMFS on those activities that may have direct (for example, physical disruption) or indirect (for example, loss of prey species) effects on EFH.

Of the FMP's for Alaskan fisheries, only the plan for salmon designates EFH present within the Alaska OCS Beaufort Sea Planning Area. The FMP's are amended and updated as new information from studies and public input is received and assessed. For OCS activities in the Alaska Region's Beaufort Sea Planning Area, the MMS consults with NMFS at each project stage individually (for example, the lease sale, the exploration plan, and the development and production plan). The MMS will enter into formal consultation with NMFS for EFH as part of this EIS process.

D.1.m. The Endangered Species Act

The Endangered Species Act (ESA) of 1973, as amended (16 U.S.C. § 1531 et seq.), establishes the National policy for the protection and conservation of threatened and endangered species and the ecosystems on which they depend. The ESA is administered by USDOI, FWS and the USDOC, NMFS. Section 7 of the ESA (16 U.S.C. § 1536) governs interagency cooperation and consultation requiring Federal Agencies to formally consult with the NMFS and FWS, when there is a reason to believe that a species listed (or proposed to be listed) as endangered or threatened may be affected by an action, such as an OCS lease sale. Section 7 mandates Federal Agencies to consult with the FWS or NMFS to ensure that any agency action is not likely to jeopardize the continued existence of any endangered or threatened species, and/or destroy or adversely modify an endangered or threatened species' critical habitat.

Formal endangered species consultation is required to provide a threshold examination and to allow both the FWS and NMFS to each prepare a biological opinion on the likelihood that the proposed activity will or will not jeopardize the continued existence of the resource, and on the effect of the potential activities on the endangered species. The biological opinion may include recommendations for modification of the proposed activity. If, as a result of the threshold examination, insufficient information is available to conclude that the proposed activity is not likely to jeopardize the species or its habitat, the Federal Agency (i.e., MMS) is notified in writing by the FWS or NMFS. In such cases, the Federal Agency must obtain additional information and, if recommended by the FWS or NMFS, conduct appropriate biological surveys or studies to determine how the proposed activity may affect the endangered species or its critical habitat. After such additional information is received, FWS or NMFS usually concludes the consultation process by issuing a formal biological opinion.

As needed during the early stages and throughout prelease processes, the MMS will formally consult with both FWS and NMFS to ensure that the Federal activities proposed in the Beaufort Sea Planning Area do not jeopardize the continued existence of threatened or endangered species and/or result in adverse modification or destruction of their critical habitat. This consultation covers only the proposed OCS lease sales and exploration activities scenarios. A separate Section 7 consultation is conducted for development, production, and decommissioning phases for OCS activities. The FWS and NMFS make recommendations regarding modifications to proposed OCS activity to minimize adverse environmental impacts; however, it remains the responsibility of the MMS to ensure that proposed actions do not impact threatened or endangered species.

Joint regulations published in 50 CFR § 402 by the USDOI (FWS) and the USDOC (NMFS) establish procedures and rules governing interagency consultation under Section 7 of the ESA.

Section 9 of the ESA (16 U.S.C. § 1538) contains prohibitions (except as provided in law) with respect to any endangered species of fish, wildlife, and plant. For example, it is unlawful for any person subject to the jurisdiction of the U.S. to (1) take any species within the U.S. or the territorial seas of the U.S. and (2) take any species upon the high seas. The term "take" means to harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or attempt to engage in any such conduct.

The regulations that provide the rules for determining and listing endangered and threatened species and designating their critical habitats are found under 50 CFR § 424.

D.1.n. The National Historic Preservation Act

The National Historic Preservation Act (NHPA) of 1966, as amended (16 U.S.C. § 470 et seq.), established a program for the preservation of historic properties throughout the U.S. and established the Advisory Council on Historic Preservation. This Act requires the head of any Federal Agency possessing licensing authority or having direct or indirect jurisdiction over a proposed Federal or federally assisted activity to consider the proposed activity's effect on any district, site, building, structure, or object that is included in or eligible for inclusion in the National Register of Historical Places (30 CFR 60.4 or its successor). The historic properties (i.e., archaeological resources) on the OCS include historic shipwrecks, sunken aircraft, lighthouses, and prehistoric archaeological sites that have become inundated due to the 120-meter rise in global sea level since the height of the last ice age (about 19,000 years ago).

Because the OCS is not federally owned land and the Federal Government has not claimed direct ownership of historic properties on the OCS, the MMS has the authority under Section 106 of the NHPA only to ensure that any MMS funded and permitted actions do not adversely affect significant historic properties. Beyond avoidance of adverse impacts, the MMS does not possess the legal authority to manage the historic properties on the OCS.

The MMS has conducted archaeological baseline studies of the OCS to determine where known historic properties may be located and to outline areas where presently unknown historic properties may be located. These baseline studies are used to identify "archaeologically sensitive" areas that may contain significant historic properties. When proposing a Federal action (i.e., an oil and gas lease sale), the MMS may request comments concerning geological conditions, including archaeological sites on the seabed or nearshore (30 CFR 256.24).

Before approving any OCS exploration or development activities within an archaeologically sensitive area, the MMS requires the lessee to conduct a marine remote-sensing survey and to prepare an archaeological report (30 CFR 250.194).

Archaeological surveys are required both onshore and offshore in areas where there is the potential for archaeological resources to exist, so that potential impacts to archaeological resources from physical disturbance could be mitigated. If the marine remote-sensing survey indicates any evidence of a potential historic property, the lessee must either:

> move the site of the proposed lease operations a sufficient distance to avoid the potential historic property, or conduct further investigations to determine the nature and significance of the potential historic property. If further investigation determines that there is a significant historic property within the area of proposed OCS operations, NHPA consultation procedures are followed.

The MMS Alaska Region and the State of Alaska Historic Preservation Office have an agreement regarding procedures for invoking Section 106 of the NHPA.

The MMS responsibilities in archaeological resource management and protection on the OCS are found under 30 CFR 250.203(b)(15), 250.203(o), 250.204(b)(8)(v)(A), 250.204(s), 250.1007(a)(5), and 250.1009(c)(4).

D.1.o. The Oil Pollution Act

The Oil Pollution Act of 1990 (OPA 90), as amended (33 U.S.C. § 2701 et seq.), establishes a single uniform Federal system of liability and compensation for damages caused by oil spills in U.S. navigable waters. The OPA 90 requires removal of spilled oil and establishes a national system of planning for and responding to oil-spill incidents. The OPA 90 includes provisions to:

- improve oil-spill prevention, preparedness, and response capability;
- establish limitations on liability for damages resulting from oil pollution;
- provide funding for natural resource damage assessment;
- implement a fund for the payment of compensation for such damages; and
- establish an oil pollution research and development program.

The U.S. Coast Guard is responsible for enforcing vessel compliance with OPA 90. The U.S. Coast Guard regulations on the oil-spill liability of vessels and operators are found under 33 CFR §§ 132, 135, and 136.

Section 1016 of OPA 90 (33 U.S.C. § 2716), as amended by the Coast Guard Authorization Act of 1996, supersedes the offshore oil-spill financial-responsibility provision of Title III of the OCS Lands Act Amendments of 1978, previously administered by the U.S. Coast Guard. Under OPA 90 and Executive Order 12777 (October 18, 1991), the Secretary of the Interior is given authority over covered offshore facilities and associated pipelines (except deepwater ports) for all Federal and State waters, including responsibility for spill prevention, oil-spill-contingency plans, oil-spill-containment and -cleanup equipment, financial-responsibility certification, and civil penalties. The Secretary delegated this authority to the MMS.

The MMS regulations found under 30 CFR § 253 that implement Title I of the OPA 90 establish the requirements for demonstrating oil-spill financial responsibility for covered offshore facilities requiring responsible parties to demonstrate they can pay for cleanup and damages caused by facility oil spills. These regulations govern financial responsibility requirements for oil spills for covered offshore facilities and related requirements for certain crude oil wells, production platforms, and pipelines located in the OCS and certain State waters became effective in October 1998. Responsible parties can be required to demonstrate as much as $150 million in oil-spill financial responsibility if the MMS determines that it is justified by the risks from potential oil spills from the covered offshore facilities. The minimum amount of oil-spill financial responsibility that must be demonstrated is $35 million for covered offshore facilities located in the OCS, and $10 million for covered offshore facilities located in State waters. The regulations exempt persons responsible for facilities having a potential worst-case, oil-spill discharge of 1,000 barrels or less, unless the risks posed by a facility justify a lower threshold.

D.1.p. The Rivers and Harbors Appropriation Act

The geographic jurisdiction of the Rivers and Harbors Act of 1899 (33 U.S.C. § 401 et seq.) includes all navigable water of the U.S. (defined in 33 CFR § 329) as "those waters that are subject to the ebb and flow of the tide and/or are presently used, or have been used in the past, or may be susceptible to use to transport interstate or foreign commerce." This jurisdiction extends seaward to include all ocean waters within a zone 3 nautical miles from the coastline (the "territorial seas"). Limited authorities extend across the OCS for artificial islands, installations, and other devices (43 U.S.C. § 333 (e)).

Various sections of the Act establish permit requirements to prevent unauthorized obstruction or alteration of any navigable water of the U.S. The Corps of Engineers, through the Secretary of the Army, has permitting authority for any structure work conducted in or affecting U.S. navigable waters and for construction of artificial islands, fixed structures, and other installations on the OCS. This authority arises from a provision in the OCS Lands Act (43 U.S.C. § 1333(e)) that extends the Secretary of the Army's authority to prevent obstruction to navigation in U.S. navigable waters from structures located on the OCS that are used for exploring, developing, producing, or transporting natural resources.

In addition, Section 10 of the Act (33 U.S.C. § 403) authorizes the Corps of Engineers, through the Secretary of the Army, to issue permits for all offshore construction in U.S. navigable waters, including pipelines, exploratory drilling vessels, fixed and mobile platforms, piers, wharves, bulkheads, or other works. Permits also must be issued for onshore facilities that involve dredging, filling, and excavating in U.S. navigable waters.

D.1.q. The Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (RCRA) of 1976 (42 U.S.C. § 6901 et seq.), and as amended through 1996, provides a framework for the safe disposal and management of hazardous and solid wastes. Most oil-field wastes have been exempted from coverage under the RCRA hazardous-waste regulations. Any hazardous wastes generated on the OCS that are not exempt must be transported to shore for disposal at a hazardous-waste facility.

D.1.r. The Ports and Waterways Safety Act

The Ports and Waterways Safety Act of 1972, as amended (33 U.S.C. § 1221 et seq.), authorizes the U.S. Coast Guard to designate safety fairways, fairway anchorages, and traffic separation schemes to provide unobstructed approaches through oil fields for vessels using ports. The Coast Guared regulations provide listings of these designated areas along with special conditions related to oil and gas production. In general, no fixed structures such as platforms are allowed in fairways. Temporary underwater obstacles such as anchors and attendant cables or chains attached to floating or semisubmersible drilling rigs may be placed in a fairway under certain conditions. Fixed structures may be placed in anchorages, but the number of structures is limited.

The Coast Guard regulations on port access routes are found under 33 CFR § 164.

D.1.s. The Merchant Marine Act of 1920 (Jones Act)

The Merchant Marine Act of 1920, commonly referred to as the Jones Act (P.L. 66-261), regulates coastal shipping between U.S. ports and inland waterways. The Act provides that "no merchandise shall be transported by water, or by land and water…between points in the United States…in any other vessel than a vessel built in and documented under the laws of the United States and owned by persons who are citizens of the United States…" The Act requires that all goods shipped between different ports in the U.S. or its territories must be:

- • carried on vessels built and documented (flagged) in the U.S.,
- • crewed by U.S. citizens or legal aliens licensed by the U.S. Coast Guard, and
- • owned and operated by U.S. citizens.

The rationale behind the Jones Act and earlier sabotage laws was that the U.S. needed a merchant marine fleet to ensure that its domestic waterborne commerce remains under government jurisdiction for regulatory, safety, and national defense considerations. The same general principles of safety regulations are applied to other modes of transportation in the U.S. While other modes of transportation can operate foreign-built equipment, these units must comply with U.S. standards. However, many foreign-built ships do not meet the standards required of U.S.-built ships and, thus, are excluded from domestic shipping.

The U.S. Customs Service has determined that facilities fixed or attached to the OCS for the purpose of oil exploration, as described under 43 U.S.C. § 333(a), are considered points within the U.S. The OCS oil facilities are considered U.S. sovereign territory and fall under the requirements of the Jones Act. This carries the implication that all shipping to and from these facilities related to oil exploration on the OCS can be conducted only by vessels meeting the requirements of the Jones Act. Therefore, OCS facilities can be legally served only by U.S.-registered vessels and aircraft that are properly endorsed for coastwise trade under the laws of the U.S.

D.1.t. The Federal Oil and Gas Royalty Management Act

The Federal Oil and Gas Royalty Management Act (FOGRMA) of 1982 (30 U.S.C. § 701 et seq.), was enacted to ensure that all oil and gas originating on public land and on the OCS are properly accounted for under the direction of the Secretary of the Interior. This Act defines the responsibilities and obligations of lessees, operators, and other persons involved in the transportation of oil and gas from Federal, Indian, and OCS lands. The Secretary of the Interior has the responsibility to maintain a royalty management system and enforce the prompt collection and disbursement of oil and gas revenues owed to the U.S., Indian lessors, and the states.

The Secretary of the Interior oversees a comprehensive inspection and collection system with fiscal and production accounting and auditing system to accurately determine oil and gas royalties, interest, fines, penalties, fees, deposits, and other payments owed and to collect and account for the payments in a timely manner.

The FOGRMA requires a lessee, operator, or other person directly involved in the developing, producing, transporting, purchasing, or selling of oil and gas to establish and maintain records, make reports, and provide information as required by the Secretary of the Interior.

Regulations at 30 CFR 201 through 243 were published by the MMS to implement the provisions of the FOGRMA. For royalties, net profit shares, and rental payments on Federal OCS leases, see 30 CFR 218.150 through 156.

D.1.u. The Arctic Research and Policy Act

The Arctic Research and Policy Act of 1984 (15 U.S.C. § 4101 et seq.) provides national policy, priorities, and goals and a Federal program plan for basic and applied scientific research with respect to the Arctic, including natural resources and materials, physical, biological and health sciences, and social and behavioral sciences.

The Arctic Research Commission, in cooperation with the Interagency Arctic Research Policy Committee, both established under this Act, were directed to develop a national arctic research program plan to implement the arctic research policy and facilitate cooperation between the Federal Government and State and local governments with respect to research in the Arctic. The Commission guides the Interagency Arctic Research Policy Committee in the performance of its duties and submits to the President and Congress a report each year describing the activities and accomplishments of the Commission during the immediately preceding fiscal year.

The Interagency Arctic Research Policy Committee, with the National Science Foundation as lead agency, works with the Commission in developing and establishing an integrated National Arctic Research Policy that guides Federal Agencies in developing and implementing their research program in the Arctic. The public is provided with an opportunity to participate in the development and implementation of National Arctic Research Policy through public meetings. The Committee is directed to submit to Congress, through the President, a biennial statement of activities and accomplishments of the Interagency Committee and a description of the activities of the Commission with respect to Federal activities in arctic research.

Section 201 of the Arctic Research and Policy Act is cited as the National Critical Materials Act of 1984. The purpose of this section is to (1) establish National Critical Material Council, (2) establish a national

Federal program for advanced materials research and technology, and (3) to stimulate innovation and technology use in basic as well as advanced materials industries.

D.2. EXECUTIVE ORDERS

D.2.a. Executive Order 13212 - Actions to Expedite Energy-Related Projects (May 18, 2001)

Executive Order 13212 states that "… in order to take additional steps to expedite the increased supply and availability of energy to our Nation …," it is necessary to improve the Federal Government's internal management of actions associated with energy-related projects. In general, the executive order directs executive departments and agencies to take appropriate actions to expedite projects that will increase the production, transmission, or conservation of energy. Departments and agencies must expedite their review of permits or take other actions as necessary to accelerate the completion of such projects while maintaining safety, public health, and environmental protections. Agencies must take such actions to the extent permitted by law, theregulations, and where appropriate.

D.2.b. Executive Order 12898 - Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations (February 11, 1994)

Executive Order 12898 on environmental justice provides that each Federal Agency must make achieving environmental justice part of its mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of its programs, policies, and activities on minority populations and low-income populations.

Agencies are required to incorporate into their NEPA documents analysis of the environmental effects of their proposed action on minorities and low-income populations and communities. The environmental justice issues encompass a broad range of impacts covered by NEPA, and concerns may arise from impacts on the natural or physical environment or from interrelated social, cultural, and economic effects. These effects must be considered in EIS's and EA's.

The Department of the Interior has developed guidelines in accordance with Executive Order 12898 on environmental justice. The MMS participated in the development of these guidelines. In August 1994, the Secretary of the Interior directed the Department's bureaus to include environmental justice in NEPA documentation and, in February 1998, the CEQ issued guidance to assist Agencies in addressing environmental justice.

Environmental justice concerns are considered anywhere (including the MMS Pacific and Gulf of Mexico regions) where OCS projects and associated NEPA documentation take place; however, issues concerning Alaska OCS-related impacts primarily have focused on the subsistence hunting, fishing, and gathering activities that occur in coastal areas.

The MMS's existing process of involving all affected communities, Native Alaskans, and minority groups in the NEPA compliance process meets the intent and spirit of Executive Order 12898. Scoping and review for the EIS is an open process that provides an opportunity for all participants, including minority and low-income populations, to express concerns that can be addressed in the EIS. It should be emphasized that the reason the MMS holds scoping meetings is to encourage and facilitate public involvement into the EIS process. Valuable public input ensures that the EIS will be thorough and will address all pertinent issues that affect the quality of the human environment to the fullest extent possible and that will contribute a major role in the MMS's planning and final decisionmaking. The MMS will continue to identify ways to improve the input from all Alaskan residents, not only in commenting on official documents but also contributing their knowledge to the scientific and analytical sections of the EIS.

D.2.c. Executive Order 13175 - Consultation and Coordination With Indian Tribal Governments (November 6, 2000)

The United States has a unique legal relationship with Indian tribal governments as set forth in the Constitution of the United States, treaties, statutes, Executive Orders, and court decisions. Since the formation of the Union, the United States has recognized Indian tribes as domestic dependent nations under its protection. The Federal Government has enacted numerous statutes and promulgated numerous regulations that establish and define a trust relationship with Indian tribes.

To strengthen the United States government-to-government relationships with Indian tribes (Indian tribe is defined as Indian or Alaska Native tribe, band, nation, pueblo, village, or community that the Secretary of the Interior acknowledges to exist as an Indian tribe pursuant to the Federally Recognized Indian Tribe List Act of 1994, 25 U.S.C. 479a), Executive Order 13175 requires the Secretary of the Interior to establish regular and meaningful consultation and collaboration with Indian tribal officials in the development of Federal policies that have tribal implications. Policies that have tribal implications refers to regulations, legislative comments or proposed legislation, and other policy statements or actions that have substantial direct effects on one or more Indian tribes, on the relationship between the Federal Government and Indian tribes, or on the distribution of power and responsibilities between the Federal Government and Indian tribes. The United States continues to work with Indian tribes on a government-to-government basis to address issues concerning Indian tribal self-government, tribal trust resources, and Indian tribal treaty and other rights.

D.2.d. Executive Order 13007- Indian Sacred Sites (May 24, 1996)

The Indian Sacred Sites executive order directs Federal land-managing agencies to accommodate access to, and ceremonial use of, Indian sacred sites by Indian religious practitioners and to avoid adversely affecting the physical integrity of such sacred sites. It is MMS's policy to consider the potential effects of all aspects of plans, projects, programs, and activities on Indian sacred sites, and to consult, to the greatest extent practicable and to the extent permitted by law, with tribal governments before taking actions that may affect Indian sacred sites located on Federal lands.

D.2.e. Executive Order 12114 - Environmental Effects Abroad(January 1979)

Executive Order 12114 requires that Federal officials be informed of environmental considerations, and take those considerations into account when making decisions on major Federal actions that could have environmental impacts anywhere beyond the borders of the U.S., including Antarctica. Such Federal actions include the following:

- All major Federal actions significantly affecting the environment outside the jurisdiction of any nation (the oceans or Antarctica). This would apply to proposals that result in actions within the U.S. that, because of ocean currents, winds, stream flow, or other natural processes, may affect parts of the oceans not claimed by any nation (high seas). Included in this category would be an OCS project that, because of ocean currents, could result in effluents or spilled oil reaching fishing grounds or areas not claimed by another nation.
- All major Federal actions significantly affecting the environment of a foreign nation not involved in the action. This would apply to proposals that result in actions within U.S. territory, or within the EEZ that, because of ocean currents, winds, stream flow, or other natural processes, may affect parts of another nation, or seas or oceans within the jurisdiction of other nations. This category would include an OCS project located upcurrent from the Mexican coastline that could affect Mexico's territory in the

event of an oil spill. Also in this category are all major Federal actions in which a foreign nation is a participant and that normally would be covered by the EIS addressing the U.S. part of the Proposal. An example would be an OCS right-of-way pipeline bringing Canadian energy resources to the northeast U.S.

- All major Federal actions providing a foreign nation with a product or involving a project that produces an emission or effluent prohibited or regulated by U.S. Federal law because of its effects on the environment or the creation of a serious public health risk.

Federal actions causing significant impacts on environments outside the U.S. are to be addressed in:

- • EIS's (generic, program [5-year OCS programmatic EIS]), and project-specific (OCS lease-sale EIS);
- • documents prepared for decisionmakers containing reviews of environmental issues involved in Federal actions, or summaries of environmental analyses (for example, OCS lease-sale decision documents, Records of Decision); and
- • environmental studies or research prepared by the U.S. and one or more foreign nations, or by an international body in which the U.S. is a member or participant.

The U.S., Canada, and Mexico are negotiating a Transboundary Environmental Impact Assessments (TEIA) Agreement through the North Atlantic Free Trade Agreement (NAFTA) Commission on Environmental Cooperation (CEC). The CEC deals with a wide range of environmental and natural resource protection issues common to Canada, the U.S., and Mexico. Developing a TEIA process is one of the requirements of the 1991 North American Agreement on Environmental Cooperation. Under this agreement, a transboundary environmental impact is any impact on the environment within the area under the jurisdiction of Canada, the U.S., or Mexico caused by a proposed project, the physical origin of which is situated wholly or in part within the area under the jurisdiction of one of the three countries. For example, a proposed project on the U.S. OCS that, because of ocean currents, winds, or proximity to the Mexican coastline, could affect Mexican waters (fishing industry, fish resources, etc.) or the Mexican coastline (oil-spill contacts, etc.) would be a project considered to have the potential to cause transboundary environmental impacts. The agreement recognizes that there is a significant bilateral nature to many transboundary issues and calls upon the three countries to develop an agreement to:

- • assess the environmental impacts of proposed projects in any of the three countries party to the agreement (NAFTA) that would be likely to cause significant adverse transboundary impacts within the jurisdiction of any of the other parties;
- • develop a system of notification, consultation, and sharing of relevant information between countries with respect to such projects; and
- • give consideration to mitigating measures to address the potential adverse effects of such projects.

Negotiations are under way between the three parties to the agreement, but the final language has yet to be worked out. Because the requirements of the assessment portion of the agreement are somewhat similar to the requirements imposed by Executive Order 12114 (i.e., impacts to foreign territory must be addressed in NEPA documents), the MMS requires that EIS's prepared on major Federal OCS actions contain an assessment of potential significant impacts to foreign territory.

D.2.f. Executive Order 13158 - Marine Protected Areas (May 26, 2000)

Executive Order 13158 defines Marine Protected Areas (MPA's) as any area of the marine environment that has been reserved by Federal, State, territorial, tribal, or local laws or regulations to provide lasting protection for part or all of the natural and cultural resources therein.

This executive order directs Federal Agencies to work closely with State, local, and nongovernmental partners to create a comprehensive system of MPA's "representing diverse U.S. marine ecosystems, and the Nation's natural and cultural resources." Ultimately, the MPA system will include new sites, as well as enhancements to the conservation of existing sites. Five principal components of this executive order are:

1. **National MPA List**: The USDOC and the USDOI will develop and maintain a National list of MPA's in U.S. waters. Candidate sites for the list are drawn from existing programs for Federal,

tribal, State and local protected areas. When completed, the list and the companion data on each site will serve several purposes such as ensuring that agencies "avoid harm" to MPA's, providing a foundation for the analysis of gaps in the existing system of protections, and helping improve the effectiveness of existing MPA's.

2. **The MPA Web Site**: The USDOC and USDOI will develop and maintain a publicly accessible web site to provide information on MPA's and Federal Agency reports required by Executive Order 13158. Also, the web site will be used to publish and maintain the National MPA List and other useful information, such as maps of MPA's; a virtual library of MPA reference materials, including links to other web sites; information on the MPA Advisory Committee; activities of the National MPA Center; MPA program summaries; and background materials such as MPA definitions, benefits, management challenges, and management tools.
3. **The MPA Federal Advisory Committee**: This committee was created to provide expert advice on, and recommendations for, a national system of MPA's. This advisory committee will include non-Federal representatives from science, resource management, environmental organizations, and industry.
4. **The Mandate to Avoid Harmful Federal Actions**: This mandate directs Federal Agencies to avoid harm to MPA's or their resources through activities that they undertake, fund, or approve.
5. **The MPA Center**: The executive order directs NOAA to create an MPA Center. In cooperation with the USDOI and working closely with other organizations, the MPA Center will coordinate the effort to implement the executive order and will:
   - develop the framework for a national system of MPA's;
   - coordinate the development of information, tools, and strategies;
   - provide guidance that will encourage efforts to enhance and expand the protection of existing MPA's and to establish or recommend new ones;
   - coordinate the MPA web site;
   - partner with Federal and non-Federal organizations to conduct research, analysis, and exploration;
   - help maintain the National MPA List; and
   - support the MPA Advisory Committee.

D.2.g. Executive Order 13112 - Invasive Species (February 3, 1999)

Executive Order 13112 defines an "invasive species" as a species that is not native (or alien) to the ecosystem under consideration and whose introduction causes or is likely to cause economic or environmental harm or harm to human health. This executive order requires all Federal Agencies to:

- identify any actions affecting the status of invasive species;
- prevent invasive-species introduction;
- detect and respond to and control populations of invasive species in a cost-effective and environmentally sound manner;
- monitor invasive-species populations accurately and reliably;
- provide for restoration of native species and habitat conditions in invaded ecosystems;
- conduct research on invasive species and develop technologies to prevent introduction and provide for environmentally sound control of invasive species;
- promote public education on invasive species and the means to address them; and,
- refrain from authorizing, funding, or carrying out actions that are likely to cause or promote invasive species introduction or spread, unless the Federal Agency has determined that the benefits of such actions clearly outweigh the potential harm caused by invasive species and that all feasible and prudent measures to minimize risk of harm will be taken.

Additionally, this executive order established the National Invasive Species Council (Council), cochaired by the Secretaries of Agriculture, Commerce, and the Interior and comprised of the Secretaries of State, Treasury, Defense, and Transportation, and the Administrator of the Environmental Protection Agency. The Council:

- provides national leadership on invasive species;
- sees that Federal efforts are coordinated and effective;
- promotes action at local, State, tribal, and ecosystem levels;
- identifies recommendations for international cooperation;
- facilitates a coordinated network to document and monitor invasive species;
- develops a web-based information network;
- provides guidance on invasive species for Federal Agencies to use in implementing the NEPA; and
- prepares an Invasive Species Management Plan to serve as the blueprint for Federal action to prevent introduction; provide control; and minimize economic, environmental, and human health impacts of invasive species.

The MMS requires that EIS's prepared on major Federal OCS actions (for example, 5-year OCS program and OCS lease sales) contain an assessment of the proposed action's contribution to the invasive species problem.

D.3. MITIGATION MEASURES

D.3.a. Lease Term Stipulations

In each OCS planning area, oil and gas exploration and development activities have the potential for causing adverse environmental impacts. Many measures have been implemented by the MMS to "mitigate" or prevent and lessen possible impacts on environmental resources from both OCS and non-OCS activities. Mitigating measures are protective measures designed to prevent adverse impacts and to lessen and mitigate unavoidable impacts. Some of these protective measures are developed and applied to specific blocks in a planning area before leasing a block. The MMS develops and administers these requirements, which become a part of the lease-term conditions at lease issuance.

If a block is leased as a result of a lease sale, these protective measures are identified as lease-term stipulations and are attached to and become part of the lease and its conditions. These stipulations are designed to protect potentially sensitive resources in the affected block and to reduce possible multiple-use conflicts and are the requirements that the lessee must meet to mitigate adverse impacts. They also may be considered to apply to all activities that occur on the leased area throughout the life of the lease.

All stipulations are considered part of this proposed Federal action. All lease-term stipulations are considered part of this proposed Federal action and all alternatives are discussed in this EIS.

D.3.b. Special Stipulations

To mitigate adverse environmental impacts for actions associated with a specific project (i.e., proposed plans for exploration, development and production plans, and site-clearance activities in an area located on an OCS lease block), mitigating measures may be necessary. Mitigating measures are special stipulations that limit OCS operations and are in addition to the aforementioned lease-term stipulations.

Conditions of plan approval are mechanisms determined by the MMS to control or mitigate potential environmental or safety problems that are associated with a specific proposed Federal action. During the life of the action, these protective measures are applicable specifically to the individual activities proposed in a plan and are imposed following environmental reviews (according to the NEPA) of the OCS lease location and potential resources.

Protective measures for certain resources may be suggested or identified during the scoping process for this EIS and mitigating measures may develop as a result. The MMS will evaluate additional stipulations, if any, that may develop during this EIS process.

APPENDIX E

SCOPING REPORT: BEAUFORT SEA PROPOSED OIL AND GAS LEASE SALES 186 (2003), 195 (2005), AND 202 (2007)

APPENDIX E: SCOPING REPORT: BEAUFORT SEA PROPOSED OIL AND GAS LEASE SALES 186 (2003), 195 (2005), AND 202 (2007)

A. Introduction

A.1. Purpose

This report summarizes scoping comments received and the significant environmental issues, reasonable alternatives for analysis, and potential mitigating measures that will be examined in the Minerals Management Service's (MMS's) environmental impact statement (EIS) for the proposed Beaufort Sea Outer Continental Shelf Lease Sales 186, 195, and 202 in the Beaufort Sea Planning Area.

A multiple-sale prelease process has been implemented for the Beaufort Sea sales in the proposed final 2002-2007 5-year program. From the initial step in the process (the Call for Information and Nominations [Call], and the Notice of Intent to Prepare an EIS [NOI]) through the final EIS/Consistency Determination step, this process covers proposed multiple sales. A multiple-sale EIS will analyze the first proposed sale (Sale 186) and the effects of the subsequent two proposed sales (Sale 195 and Sale 202). There also will be complete National Environmental Policy Act (NEPA) and Coastal Zone Management Act coverage for all sales after the first sale; either an Environmental Assessment (EA) or supplemental EIS, and a Consistency Determination (focusing primarily on new issues or changes in a State's federally approved coastal management plan) will be prepared for each subsequent sale. A proposed and final Notice of Sale will be prepared for each proposed lease sale identified in the draft proposed program.

One of the key features of the prelease process is the preparation of a multiple-sale EIS. One EIS covers three lease sales: Sale 186 scheduled for 2003; Sale 195 scheduled for 2005; and Sale 202 scheduled for 2007, according to the release of the 2002-2007 5-Year proposed final program. This will enable the MMS to conduct the prelease decision processes for subsequent sales (Sales 195 and 202) more efficiently, consistent with the new Executive Order of May 18, 2001, to expedite energy-related projects. Federal regulations (40 CFR 1502.4) allow several similar proposals to be analyzed in one EIS. The EIS will include: (a) an analysis for each of the three Beaufort Sea sales; (b) an analysis of the three sales collectively; and (c) a cumulative analysis of the incremental effects of holding the three sales when added to the other past, present, and reasonably foreseeable State and Federal onshore and offshore oil and gas activities on the North Slope and other activities that could affect the same resources.

This EIS will have a specific analysis for all issues, alternatives, and mitigating measures developed during the assessment process. Issues, alternatives, and mitigating measures that were determined to be insignificant will not be examined in the EIS but are identified in Sections II.B and IV of this report.

B. Summary of the Scoping Process

Scoping for the Beaufort Sea multiple-sale EIS included:

- reviewing the comments received from the Call/NOI;
- reviewing comments from scoping meetings;
- re-evaluating issues raised and analyzed in the EIS's for previous Beaufort Sea Planning Area lease sales (Sales BF, 71, 87, 97, 124, 144, and 170); and
- soliciting staff input.

Scoping comments for the proposed lease sale were requested from the public through newspaper, radio, and television advertisements in the North Slope Borough (NSB) communities of Barrow, Nuiqsut, and Kaktovik, and in Anchorage. The Call/NOI and scoping process provided a forum in which a wide variety of professionals and private citizens representing a broad spectrum of concerned groups had the opportunity to review and comment on areas of concern and appropriate areas for future studies. Environmental Justice was discussed with participants on the North Slope, both in the Government-to-Government meetings and with individual participants at the scoping meetings. The MMS provided an Inupiat translator for scoping meetings held on the North Slope to facilitate communication and comments. A Notice of Intent to prepare an EIS was published in the *Federal Register* on September 19, 2001, and comments were due by November 5, 2001.

B.1. Comments Received in Response to the Call/NOI and the Scoping Process

The MMS received nine written comments through the Call/NOI and scoping process from the following: State of Alaska, Office of the Governor, Division of Governmental Coordination; North Slope Borough, Office of the Mayor; North Slope Borough, Planning Department Director; Alaska Eskimo Whaling Commission, Director; City of Wainwright, Mayor; combined letter from the Sierra Club, Arctic Connections, the Wilderness Society, and Greenpeace; Phillips Alaska Exploration; Shell Oil; and British Petroleum (Alaska) Inc.

Specific Comments: Specific concerns expressed in the letters received in response to the Call/NOI are summarized in the following.

B.1.a State of Alaska, Office of the Governor, Division of Governmental Coordination

- The State supports the deferrals and mitigating measures that have been incorporated into previous outer continental shelf (OCS) lease sales.
- The State supports the Barter Island deferral that was included in Sale 144. This deferral area did not apply in Sale 170.
- The State recommends that the MMS retain the conflict avoidance measures developed for Lease Sale 170, especially in regard to subsistence resources. The Cross Island Stipulation for protection of subsistence resources in the Cross Island area should be retained.
- The Information to Lessees (ITL's) adopted for Sale 170 also should be included for the upcoming sales. The MMS may wish to consider expanding the ITL on polar bear interaction to include brown bears to minimize conflicts between bears and humans that might arise on onshore facilities associated with onshore development.
- The Alaska Department of Natural Resources and the Alaska Department of Fish and Game expressed support for a single EIS covering all three sales. However, the North Slope Borough opposes this change, and the State encourages MMS to work with the North Slope Borough to address their concerns before switching to a multiple-sale process.
- The State recommends that the MMS use the existing process for the coastal consistency review for the upcoming sales.

B.1.b North Slope Borough, Office of the Mayor

- There should be a full public process associated with each sale.
- An EIS should be developed, and a Coastal Management Program Consistency Analysis should be conducted for each sale.
- The MMS and other State and Federal leasing agencies are moving ahead with their plans without a good handle on the cumulative impacts of all of this (other related oil and gas activities) on the environment, wildlife resources, and residents of the North Slope. Serious cumulative impacts already have occurred.
- Areas deferred from past Beaufort Sea sales should be removed permanently from consideration for leasing.
- The spring-lead system and eastern Beaufort Sea should be deferred from leasing in all Beaufort Sea sales under the proposed 2002-2007 OCS leasing program. The spring-lead system around Point Barrow concentrates and renders highly vulnerable a variety of arctic marine resources. It is a critical subsistence-use area.
- The eastern Beaufort Sea is a feeding area for bowheads migrating westward in the fall. The level of industrial activity in waters east of Barter Island is of critical importance to the success or failure of subsistence-hunting efforts. In the past, fall exploratory drilling operations occurring to the east of the subsistence-harvest zone have deflected whales beyond the reach of subsistence hunting.
- The 10-mile distance (around Cross Island) is arbitrary and too small. The zone should be expanded to include a larger area based on the true area used by Nuiqsut in the traditional pursuit, harvest, retrieval, and processing of bowhead whales, in addition to the areas used for transportation and storage of the products of the bowhead whale hunt. This includes the areas to the east where production noise from permanent industrial facilities would have the potential to deflect whales out of reach of subsistence hunters. The goal should be to add protection for the area directly used by subsistence whalers and to the east of that area where noise from permanent industrial facilities would have the potential to deflect whales beyond the reach of subsistence whalers.
- A new whale-deferral zone should be defined in consultation with the Alaska Eskimo Whaling Commission (AEWC) and Nuiqsut and refined as noise-monitoring studies, including those associated with Northstar and Liberty, to produce more accurate information on (bowhead) impacts.

B.1.c North Slope Borough, Planning Department Director

- The NSB finds the lease sales (proposed) by MMS to be inconsistent with the policies of the NSB Coastal Management Plan and the Alaska Coastal Management Program.
- Industrial noise from seismic activities has proven to deter migrating bowhead whales by up to 12 miles.
- The continued availability of these waters for oil and gas exploration and development conflicts with (our) culture and the habitat values of the bowhead whale.
- Our culture is dependent on the continued availability of whales and our being able to hunt them close by. The spring migration area is particularly important.
- Oil-spill-cleanup trials have failed to meet response-planning standards for open-water and broken-ice conditions. The oil industry has yet to come up with a system for mechanical oil recovery that will work in ice-infested waters. It is irresponsible to continue leasing, exploratory drilling, and development in the arctic marine environment until the oil industry has demonstrated definitively that it has the capability to effectively respond to a significant oil spill in the entire range of environmental conditions that it may face in the region.
- If the need arises to provide relief-well operations in cases where a blowout or other catastrophic uncontrolled release should happen, no effective relief-well operations can occur within the unstable ice regimes that exist from 3-60 miles offshore. Completion of a relief well and well control could take 2-3 months under extreme broken-ice conditions.
- We believe that the MMS has underestimated the ice forces of the area, and that these forces could result in a significant release of oil. An ice-override event can occur at anytime when ice is present, subjecting all human activities in the area to great danger.
- The OCS from 3-60 miles offshore has not been extensively explored or studied for exploration or production activities. The placement and protection of fuel tanks, drilling rigs, and other oil and gas activities must be able to withstand the combined forces of current and wind-driven ice. These placements must be based on actual measurements of ice forces and movements.

- Other potential offshore hazards may exist, such as methane hydrate pockets. Historically, methane hydrate is responsible for the sinking of some ships and fires on or toppling of oil platforms.
- Spilled oil could persist in the migration path of the bowhead whale, with the potential to divert the animals from their preferred migratory path, or to subject the whales and other marine wildlife to the harmful effects of hydrocarbon exposure.
- The community of Nuiqsut, which uses the Cross Island area for subsistence, and other subsistence communities that use resources migrating through the Beaufort Sea, would suffer loss of resources, impaired access to resources, or the tainting of resources.
- Any perceived threat to the bowhead whale that results from a spill may elicit action by the International Whaling Commission (IWC). The IWC may reduce subsistence quotas as the only means of enhancing the protection of whale populations at risk.
- The North Slope Borough Planning Department stated that 10-mile no permanent facility area in Stipulation 6 as adopted in OCS Lease Sale 170 cannot now be developed without precluding reasonable subsistence access to fall-migrating bowhead whales.
- A study has not been forwarded to the NSB that concludes that the areas around the lease proposals can or cannot be developed, nor has (there been) any (information on) new technology in recovering oil from arctic waters (as well as) an assessment concerning subsistence-user access to subsistence resources and the effects on the (bowhead) migration path relative to Cross Island.
- The Beaufort Sea lease sales include areas 3-60 miles offshore and are in an area that cannot be developed without harming subsistence activities and the migratory route or feeding areas of the bowhead whale during the life expectancy of a field.
- Given the unpredictability of the arctic environment, opportunities for oil and gas leasing should be focused on land where proven systems exist and more accurate performance predictions can be made.

B.1.d Alaska Eskimo Whaling Commission Director

- The AEWC submitted comments to MMS on the Proposed draft 5-Year OCS Leasing Program 2002-2007 and the related EIS. The AEWC hereby incorporates those comments by reference.
- The present Notice of Proposed Lease Sales by MMS is premature, because the 5-Year OCS Leasing Program 2002-2007 has not been finalized and approved. The Secretary does not have the authority to act on planned leases that are part of a proposed leasing program until the Secretary fully complies with the notice and comment periods of the OCS Lands Act and the leasing program has reached the stage of final approval.
- MMS must address the mitigation of adverse impacts before going any further with OCS leasing in the Beaufort Sea.
- The AEWC claims that Congress gave the grant of authority in the OCS Lands Act and quotes 43 USC 1334(a): “Congress further authorized the Secretary to ‘at any time prescribe and amend such rules and regulations as he determines to be necessary and proper in order to provide for the protection of correlative rights.’” the AEWC contends that their staff time is dominated by OCS-related matters with no Government funding to help them, in spite of repeated requests for assistance. They believe that the MMS has a statutory responsibility to provide for their correlative rights. As such, they request assistance so that they may be able to fully participate in mitigation of adverse effects.
- MMS is required to prepare an EIS for each lease sale it proposes to hold. The AEWC states: that according to NEPA, “the decision whether or not to prepare an EIS comes after the preparation of an EA not before.” (MMS Note: Subsequent to the submission of this comment, the Executive Director of the AEWC acknowledged that this statement was based upon a rather unclear description of the multiple sale EIS process by MMS. MMS interprets this subsequent acknowledgement by the AEWC as a withdrawal of the previous comment)
- Areas used for our bowhead whale subsistence hunt should be permanently removed from any future consideration for OCS leasing. These removal areas must be of a size and configuration that will ensure their effectiveness as a means of mitigating adverse impacts to the bowhead whale subsistence hunt from OCS oil and gas activities.

B.1.e City of Wainwright, Mayor

- The majority of the community is opposed to leasing in the Beaufort Sea. The area available for leasing is in the path of migrating bowhead whales, and any activity in that area would interfere with the whale's migration and related subsistence activities.

B.1.f Sierra Club, Arctic Connection, Wilderness Society, and Greenpeace (joint letter)

- Industry is unable to contain and clean up oil spills in arctic waters during most of the year.
- The new subsea buried pipeline technology has unprecedented risks of oil spills.
- The environment and local communities are experiencing the simultaneous impacts of a massive surge of exploration (seismic surveys and drilling) on the North Slope as well as new offshore oil construction.
- Offshore lease sales jeopardize the integrity of the wilderness, wildlife, and coastal habitats of the Arctic National Wildlife Refuge (ANWR). The Refuge would be degraded from pollution from offshore development, transport and industrial noise, and potential oil spills.
- In the future, there would be intense pressure to construct sprawling onshore airports, pipelines, roads, docks, and other support facilities within the Refuge.
- The last Beaufort Sea Sale 170 set a precedent of not leasing off the coast of ANWR. Among the reasons cited by the Interior Department, was a lack of information on cumulative impacts on the Refuge, emergency response plans, and subsea pipelines. that lack of information still exists.
- They support a deferral requested by the city of Kaktovik, an offshore deferral area from the Canning River to the Canadian border.
- They oppose the streamlining proposal and desire the full process for each sale.
- The cumulative impacts of simultaneous onshore and offshore exploration and development must be considered.
- Areas that were deferred or deleted from past Beaufort Sea sales should be removed permanently from consideration for leasing. The importance and sensitivity of the Barrow-area spring-lead system and the eastern Beaufort Sea has been recognized in recent OCS lease sales, and the areas have been deferred from leasing. The spring-lead system and eastern Beaufort Sea should be deferred from leasing under the proposed 2002-2007 OCS leasing program.

B.1.g Phillips Alaska Exploration

- They support sales every other year covering an area within 30 miles of the shoreline.
- They do not support "discretionary sale deferrals and arbitrary exclusions." "the greater the foreseeable leasing area, the greater the incentive."
- "It is important that all nearshore acreage be included in upcoming sales."
- They encourage the MMS "to set and apply consistent and reasonable lease terms and mitigating measures for all upcoming sales."

B.1.h Shell Oil

- They support leasing the entire nearshore area out to about 15 miles.

B.1.i British Petroleum (Alaska) Inc.

- They applaud MMS's efforts to streamline the environmental review process, and they endorse the proposed Beaufort Sea sale schedule.
- They encourage the MMS to use existing EIS supporting documentation in upcoming work and coordinate information exchanges with the State of Alaska relative to research and studies already conducted in the Beaufort area.

B.2. Scoping Meetings

The Scoping Meeting for the Beaufort Sea multiple-sale EIS were held in Nuiqsut, Barrow, Kaktovik, and Anchorage on October 16, 18, 19, and 26, 2001, respectively. Meetings with the Native Village of Barrow, and the Mayor of the North Slope Borough and Alaska Eskimo Whaling Commission also were held while the scoping team was in Barrow. An additional meeting was requested by the AEWC and the Inupiat Community of the Arctic Slope (ICAS) and held on November 15, 2001. Environmental Justice concerns were accepted during the meeting held on the North Slope and those comments are included in summary of issues and concerns below. The EIS will include an Environmental Justice analysis. Following are the major concerns that were raised at these scoping meetings.

B.2.a Government-to-Government Nuiqsut Tribal Council Meeting, October 16, 2001

The meeting was held in the afternoon; five to six persons attended. The Council is concerned about the following:

- the safety of OCS activities and potential impacts from oil spills;
- the effects to subsistence resources including bowheads, seals, and fish;
- the breadth of the sale, from Barrow to Canada;
- that MMS is not using traditional knowledge when making decisions; and
- that OCS activities are impacting the local sociocultural and health systems.

The Council indicated the following:

- the preparation of a single EIS for all three sales will limit their input into the sale process;
- the MMS needs to look at the cumulative impacts and consequences of offshore leasing when making decisions; locals are not responsible for cumulative effects; and
- they also are requesting local impact assistance.

B.2.b Nuiqsut Public Scoping Meeting, October 16, 2001

The meeting was held in the evening; 31 persons attended.

- Individuals are concerned about the ability of oil companies to clean up oil. They are most concerned that three oil-spill drills have failed to pick up oil in ice-infested water under relatively mild conditions.
- The Mayor of Nuiqsut stated his concern that ice forces are capable of overriding manmade islands and can result in oil spills.
- Some expressed concern about adverse effects to their subsistence lifestyle, especially fish harvests.
- Some stated that they should have more input before the lease-sale decisions, and they feel that MMS is not using local traditional knowledge. They need to protect their natural resources—no drilling on the OCS. They support onshore drilling.
- The people of Nuiqsut want Cross Island completely deferred. The area should be permanently dropped from leasing consideration.
- Those commenting stated that the managing Federal Agencies and the oil companies should share resources found with the village.
- Others stated that:
  - MMS should fund local oversight subsistence programs,
  - bowhead whale feeding areas should be off limits to leasing,
  - industry is offering limited local job opportunities,
  - offshore pipelines which come onshore are restricting caribou movement, and
  - an EIS should be written for each Beaufort Sea sale, otherwise they will have limited input to the process.

B.2.c Government-to-Government Native Village of Barrow Scoping Meeting, October 18, 2001

The meeting was held in the morning; seven persons attended. The commenting expressed concerns about:

- industry's ability to contain a pipeline break and the long-term environmental effects from an offshore pipeline oil spill;
- the potential effects to their subsistence lifestyle;
- the lack of power the locals have to get information and learn the process; they stated that education is power;
- platform types in ice-infested waters and whether they would withstand the arctic winters; and
- circumpolar ice movement and the difficulty it adds to OCS drilling.

B.2.d Barrow Scoping Meeting with the North Slope Borough and AEWC, October 18, 2001

The meeting was held in the afternoon; seven persons attended:

- Those attending stated that they do not support the OCS program, as no efficient oil-spill cleanup technology is available. The Secretary and MMS should permanently remove from leasing and oil and gas activities those areas that are important subsistence areas, such as the spring lead system, the area near Cross Island, and the bowhead whale feeding areas.
- The NSB, AEWC, and Whaling Captains should be consulted and included in the development of mitigation and deferral areas.
- They want impact assistance and local participation in decisionmaking.
- They are concerned about oil-spill cleanup and pipeline design.
- The North Slope Borough wants to protect the food and cultural resources of the residents on the North Slope. The resources from the ocean are vital parts of the Inupiat culture.
- They view leasing, exploration, and development and production as a continuing process; one stage leads to the next with no stopping the momentum once it gets started.
- The Secretary of the Interior needs to approve the 5-year program before the MMS starts the individual lease-sale process under this program. They stated there should be an independent EIS for each lease sale. They want an independent Coastal Zone Consistency evaluation for each sale.
- They expressed concern that seismic vessels working on the northern gas route survey spooked the whales farther offshore this past year.
- MMS needs to be an advocate of the NSB positions. The MMS needs to deal with the NSB and local concerns and issues.
- MMS should require the employment of local NSB residents in OCS activities.
- The OCS Policy Committee recommended (a) funding to locals and (b) NSB oversight of the plans; this is through (1) peer review of studies material and technical material; (2) mitigation, if needed; and (3) impact funding to locals.
- They need mitigation for local economic/social impacts.
- The AEWC is against all offshore leasing, exploration, and development.
- They stated that cumulative impacts are really "snowballing" now. The NSB residents are becoming increasingly frustrated. It seems like cumulative impact is being left up to the locals to address/solve.

B.2.e Barrow Public Scoping Meeting, October 18, 2001

The meeting was held in the evening; six persons attended. Those attending stated the following:

- They are concerned about the potential adverse effects from an oil spill. They want a performance bond for catastrophic spill. They are concerned about adverse effects to fish, bowhead whales, and subsistence lifestyles.
- They wish they could repair Native sovereignty and control their own destiny in their own environment.
- They want oil and gas pipelines to be buried in the road system so pipelines will not impede caribou movement.

- They want impact assistance at the community level.

B.2.f Kaktovik Public Scoping Meeting, October 19, 2001

The meeting was held in the evening; six persons attended:

- They voiced concerns about the extensive barge traffic along the coast this summer bringing in the sewer and water pipes for their village, plus Canadian seismic boats working on the gas pipeline. Indications were that both actions seemed to push their subsistence whaling efforts farther offshore.
- They are against offshore oil and gas activities.

B.2.g Anchorage Public Scoping Meeting, October 26, 2001

The meeting was held in the evening; two persons attended:

- One individual from an environmental organization delivered a group joint letter, which is summarized earlier in this section under B.1.f on page E-5.
- The other individual, an MMS study subcontractor gave his perception of local reactions to OCS oil and gas activities.

B.2.h Barrow Meetings with Inupiat Community of the Arctic Slope and the Alaska Eskimo Whaling Commission on November 15, 2001

- The AEWC provided whale-strike information and two potential deferral alternatives, one near Barrow and one near Nuiqsut.
- The ICAS is against OCS drilling.

C. Environmental Concerns

C.1. Significant Environmental Issues

No entirely new significant environmental concerns were identified during the scoping process that was not identified in the previous Sale 170 final EIS. Since this last sale EIS, Northstar, the first partial OCS jurisdictional development and production island, has been built and has come online. This has raised feelings of environmental uncertainty by local residents, because many do not trust the engineering designs to overcome known North Slope environmental constraints. Many concerns extend to the Liberty Development and Production Project, which was under review.

The following environmental issues are identified for analysis in the EIS, because they are related to important resources, activities, systems, or programs that could be affected by petroleum exploration, development, and production, and transportation activities associated with the proposals for all three sales. The cumulative effects of present and future major activities on each of these resources, activities, systems, or programs will be analyzed.

C.1.a Effects of Spilled Oil on Marine Resources

Contamination and Effects: the likelihood of large oil spills is very small. However, if oil spilled, it could contaminate the affected marine and coastal environments and, depending on the amount and time of the year, have short- to long-term local to regional effects on those resources and sociocultural systems adjacent to the planning area. A hydrocarbon-spill event, especially a large one, could have a significant impact on water quality. In situ burning of spilled oil would affect the air quality of the region. Lower trophic-level organisms within the spill area also would be affected. Marine mammals, including the endangered bowhead whale, could be affected as they migrate through the Beaufort Sea. The bowhead whale is integral to the continuation and survival of the cultural and subsistence lifestyle of the Inupiat. Both the spectacled eider and the Steller's eider are listed as threatened species.

Other resources affected by an oil spill that are crucial to Inupiat subsistence include anadromous fish, including the Arctic cisco, and various marine and coastal birds. The Inupiat are concerned that a spill could adversely affect many of the traditional food sources and, thereby, could affect the economic and cultural well-being of the North Slope. The temporary or permanent elimination of primary subsistence foods would cause North Slope residents to either shift to less desired subsistence resources or replace them with western foods.

C.1.b Fate, Behavior, and Cleanup of Spilled Oil in the Marine Environment

The fate and behavior of spilled oil in the marine and coastal environments and the capability and methods of spill cleanup are of major concern to local communities. Identified concerns include:

- the availability and adequacy of containment and cleanup technologies, especially under broken-ice conditions;
- the ability to detect and clean up pipeline spills and spills under ice;
- the effects of winds and currents on the transport of spilled oil within ice;
- the removal of oil from contaminated water sediments and ice;
- the toxicological properties of fresh and weathering oil; and
- the air pollution that would result from the at-sea evaporation or burning of spilled oil.

This concern has been intensified in recent years, as industry has on three occasions not proved their ability to adequately clean up spilled oil with mechanical equipment in relatively calm environmental conditions in ice-infested waters. Other non-mechanical tactics are available in these periods.

Oil spills and a general discussion of oil-spill contingency plans will be covered in this EIS.

C.2. Habitat Disturbance and Alteration

Habitat disturbance and alteration might result from both offshore and onshore construction activities associated with the operation of petroleum facilities, depending on location of activities.

C.2.a Habitat Disturbance

Habitat disturbance, including noise, might be associated with air traffic, vessel operations, traffic along gravel and ice roads, marine and over-the-ice seismic activities, offshore drilling, dredging, vessels involved in icebreaking and management operations, and facility construction. The primary concern in all communities and by the North Slope Borough is interference with the bowhead whale hunt. Depending on the type of operation and the time of occurrence, these habitat disturbances may have short- to long-term local to regional effects on fishes (particularly anadromous species such as the Arctic cisco), marine and coastal birds, marine mammals, caribou, and endangered and threatened species such as the bowhead whale, Steller's eider, and spectacled eider, all of which will have an effect on subsistence hunting and fishing. Issues related to the above will be evaluated in EIS analysis for new projects when they are submitted to the MMS.

C.2.b Habitat Alteration

Habitat alteration, including reduction, would be associated with both onshore and offshore construction activities that include pipeline and ice- and gravel-road construction, dredging-excavation and dumping of dredge material, removal of gravel from onshore sites, and dumping of onshore gravel in offshore locations. Depending on the type of operation and the time and location of occurrence, they could have short- to-long-term local to regional effects on lower trophic-level organisms; fishes (especially Arctic cisco) and other anadromous species; marine and coastal birds; marine mammals; endangered bowhead whales, especially in the spring-lead system and fall-feeding area; caribou; archaeological resources; and subsistence hunting and fishing activities related to reduced access to the resources. The MMS does not have the authority to mitigate disturbances to wildlife due to onshore pipeline routing.

C.3. Protection of Inupiat Culture and Way of Life

The Inupiat believe their culture and way of life need to be protected from effects associated with petroleum development. As such, activities might lead to social disruption and a change in cultural values through employment changes (further displacement of the subsistence lifestyle by a cash economy), and the alteration of subsistence-harvest patterns as discussed in relation to other significant issues previously noted in this section. The EIS will discuss and evaluate sociocultural and health systems of local communities.

C.4. Other Significant Concerns

Following are other significant issues related to petroleum-development activities that were raised during the scoping process:

- Incorporation of "traditional knowledge" (TK) in the EIS, although acknowledged, still does not seem to satisfy those who criticize this aspect. Concern seems to center around a perception that MMS does not recognize TK on the same level as scientific knowledge. The implication is that although MMS has quoted TK within the EIS text, TK has not been a part of the decisionmaking process. Villages seemed to appreciate the fact that MMS gathered the last 25 years of public testimony and prepared a publicly available searchable CD-ROM. The MMS will continue to communicate with the AEWC and whaling captains to gain insight into local conditions. The TK (for example, about fish species and other subsistence values) will continue to be incorporated into EIS text and provided to MMS decisionmakers.
- Cumulative effects of oil and gas operations on the biological (i.e., caribou migration restricted in relation to pipeline routes, and onshore effects, including fishing in the Colville River) and physical resources and social systems (i.e., development impact to the Inupiat way of life, and no rights to visit family's ancestral ice cellars in Prudhoe Bay) in and adjacent to the planning area from past, present, and future Arctic oil and gas lease sales and other major projects, will be analyzed in the EIS. Criticism still arises from not having a definite database to tier off of before oil and gas operations even occurred on the North Slope. The National Research Council is conducting a 2-year review on cumulative effects of oil and gas operations on the North Slope. Results may be available for incorporation, as applicable, into the final EIS for this lease sale.
- Include all of the mitigating measures-stipulations and notices to lessees from the last lease sale (Sale 170) into this Beaufort Sea multiple-sale EIS.

C.5. Topics and Issues Not Analyzed in the EIS

This includes issues that were identified during the scoping process and that are not analyzed in the EIS.

C.5.a Revenue Sharing/Impact Assistance

One issue, repeatedly identified as being of primary concern to the North Slope Borough and all of the North Slope villages, is the need for revenue-sharing assistance to local communities from OCS receipts. Impact assistance beyond what is provided for under the OCS Lands Act would require congressional action and cannot be addressed or resolved through the EIS process. Under the 1997-2002 5-Year Oil and Gas Leasing Program, recommendations of the OCS Policy Committee for such revenues were passed through MMS to appropriate congressional constituents. However, it is Congress and not MMS that makes this decision. A version of this type of legislation (the CARA bill) was passed by Congress for FY 2001; however, monies derived did not filter down to the local villages. Funding was only at the State and Borough level. Locals do not like to be competing among themselves for monies they feel rightfully belong to them.

C.5.b Participation of Local Communities

The need for active participation and involvement, including decisionmaking authority, of the North Slope Borough and local communities was another issue raised at each of the scoping meetings. Examples are Borough, City, and Native village participation in the review of oil-industry operations, development of monitoring programs, and helping to write the various NEPA documents. Locals would like to be brought to Anchorage and be a part the of internal review process of industry-submitted projects. The MMS did solicit and receive Environmental Justice comments, which are included above, and the EIS will include an Environmental Justice analysis. The MMS will continue to engage local governments and tribes in government-to-government meetings to share information and will meet as often as needed to discuss potential solutions.

C.5.c Process Issues

Several commenters suggested that MMS should wait to start the individual lease-sale process until the Secretary had approved the final 5-year program for 2002-2007. They suggested it was illegal or improper for MMS to start the Beaufort Sea multiple-sale process before a final decision by the Secretary. However, to meet the proposed schedule, MMS must start the preliminary scoping and writing of the EIS based on the draft proposed program, otherwise it would be impossible to hold any sales in the first 2 years of any 5-year program. Once the proposed program is approved, adjustments will be made to any text within the draft EIS. Any 5-year program decisions concerning the Beaufort Sea Planning Area will be incorporated into this EIS and into the potential lease sale decisions for Sale 186, 195, and 202. The current proposed actions for this EIS are to conduct the three sales identified in the 2002-2007 5-Year Draft Proposed Program for the Beaufort Sea: Sale 186 to be held in 2003; Sale 195 to be held in 2005; and Sale 202 to be held in 2007. This will enable the MMS to conduct the prelease decision processes for subsequent sales (Sales 195 and 202) more efficiently, consistent with the new Executive Order of May 18, 2001, to expedite energy-related projects. Federal NEPA regulations allow several similar proposals to be analyzed in one EIS (40 CFR 1502.4). There also will be complete NEPA and Coastal Zone Management Act coverage for all sales after the first sale, either an Environmental Assessment or Supplemental EIS, and a Consistency Determination (focusing primarily on new issues or changes in a State's federally approved coastal management plan) will be prepared for each subsequent sale.

Commenters suggested that areas deferred (i.e., bowhead subsistence-hunt areas) or deleted from past Beaufort Sea sales should be removed permanently from consideration for leasing. The EIS looks at deferrals for each sale and in the areas considered in the 5-year planning process. Any 5-year program decision made by the Secretary whether to exclude or to continue to exclude areas will be incorporated into this EIS.

A suggestion was made that MMS have industry provide job opportunities and training for local communities to help their economy. Under a lease-sale or postlease-sale EIS, the MMS does look at and evaluate the local community in relation to the proposed actions. However, the MMS has no authority to require an operator to provide local hire. We can suggest, but not enforce, such a suggestion.

Some reviewing constituents consider a continuum between leasing, exploration, and eventual production and development phases of the Federal oil and gas-leasing program. They feel that once a decision is made to lease an area, any subsequent decisions are a "done deal" that cannot be stopped or altered. The OCS Lands Act and the regulations consider these as four separate phases, each of which has a separate decision process attached to that phase. Subsequently, there are four NEPA documents prepared for these various phases: (1) a national 5-Year leasing program EIS; (2)a leasing program EA or EIS; (3) an exploration program EA or EIS; and (4) a production and development plan EA or EIS. Each NEPA phase has a different level of analysis, depending on the specificity of the information being submitted for review. This concern is not supported by the history of leasing in the Alaskan OCS and the Beaufort Sea. Thousands of leases have been issued; however, fewer than 100 wells have been drilled and only one project, Northstar, has started production. A second project, Liberty, is under NEPA review.

C.5.d MMS Should Allow Locals to Provide Input in Development of Monitoring and Mitigation Measures and Should Provide Funding to Local Oversight Subsistence Programs

MMS will continue to consult local communities throughout the presale process about possible mitigation measures. Some involvement by locals is being considered separately, as this topic is outside the EIS process. MMS cannot obligate OCS revenues for support of local subsistence program, only Congress can appropriate funds. Please see the previous discussion of impact assistance.

C.5.e MMS and the Oil Companies Should Provide Local Communities with a Reasonable Energy Source

Commenters at the meetings on the North Slope feel that MMS should require the oil companies to provide energy to the residents of nearby local communities, which are the potential recipients of adverse impacts associated with offshore oil and gas development. Both Barrow (Barrow gas field) and Nuiqsut (from Alpine) have nearby natural gas supplies, which have been made available to local residents. Such arrangements are between the operator and the local community.

C.5.f Ice Override

Commenters at meetings in Nuiqsut and Barrow feel that proposed oil and gas activities could be adversely impacts by the movement of ice in the Arctic. A general discussion of known unstable ice regimes and historic ice-override events are included in our lease-sale EIS analysis. Specifics as to placement of fuel tanks, relief wells, and human safety factors relating to these topics are addressed in subsequent exploration plan and development and production plan analysis. The MMS takes traditional knowledge into consideration when evaluating ice forces. This procedure was used for both Northstar and Liberty development and production plans.

C.5.g Gas Hydrates

Some stated that methane-hydrate pockets might be present and a safety hazard to OCS operations. A general discussion of these phenomena is covered under the general geology section of lease sale EIS's. Specifics as to an actual drilling plan are discussed in the exploration plan or development and production plan, and are covered under MMS regulations.

C.5.h Unprecedented Subsea Buried Pipeline Technology

Some commenters stated the subsea buried pipelines are based on unproven technology, and they do not feel that such pipelines are safe. Within the lease-sale EIS, buried subsea pipelines are described and the potential effects from construction or from an oil spill are evaluated. Design criteria are set by Federal and State regulations; the operator can design as they see fit, but they must meet this criteria. The operator submits engineering analysis to back up their design specifications. The development and production plan EIS discusses the environmental effects of the overall pipeline analysis. This procedure was used for both the Northstar and Liberty development and production plans.

C.5.i Critical Habitat Should be Deleted from OCS Leasing

Some comments in Barrow suggested that the ongoing Federal process to identify and designate critical bowhead whale habitat automatically required its exclusion from consideration for future leasing. However, the designation of critical habitat requires additional analysis within the EIS and consultation with the responsible regulatory agency. This does not necessarily mean that the area designated will be automatically deleted from future leasing proposals. Therefore, the MMS suggested that these commenters provide suggestions for deferral alternatives, which they did.

C.5.j Bonding for Operators

The NSB and the AEWC both indicated that locals have required the operator to put up a performance bond for operations on the North Slope to protect their subsistence resources. They stated that local communities should not have to require bonds, because requirements for bonding are an MMS responsibility. MMS regulations do require operator bonding for financial liability on their lease, but the Oil Pollution Act of 1990 covers this.

C.5.k Bury Pipelines in North Slope Roads to Eliminate Visual Pollution and to Eliminate Blockage of Caribou Migration Routes

A commenter in Barrow was concerned that existing onshore pipelines maybe inhibiting the movement of bull caribou. Onshore pipeline routes are under the jurisdiction of the State, not MMS. Cumulative effects to caribou will be evaluated in this EIS and in future NEPA documents for any OCS oil and gas exploration or development.

D. Alternatives Recommended for Inclusion in the EIS

Six alternatives have been identified by MMS, taking into consideration the area identification and scoping process, industry interest, and publicly available information on potential effects of the proposed action on the environment.

D.1. Description of Alternative I (Proposal for Sales 186, 195, and 202)

Alternative I, the proposal for each sale, would offer for lease those blocks selected as a result of the area identification. The Beaufort Sea Multiple-Sale Program Area includes 1,877 whole or partial blocks covering 9,770,000 acres (about 3,954,000 hectares) in the Beaufort Sea, See Map 1 and 2.) This area was identified as being of high and medium interest to industry and is the entire area of the Call. This alternative reflects a range of resource development and activity from 340-570 million barrels of recoverable oil for each sale. There are 55 active leases in this area, 21 of which were leased in Sale 170. Previous sales in this area have resulted in 688 leases; of these, 623 have been relinquished or have expired. A total of 30 wells have been drilled, and 10 wells have been found producible, but only two development proposals (Northstar and Liberty) have been submitted to the MMS. Two Federal leases are part of the Northstar Unit that went into production in November 2001. Recently, British Petroleum (Alaska), Inc. (BPXA) put the plan for development and production of the Liberty Prospect on hold but, because the final EIS essentially was completed, it was published in May 2002.

D.2. Alternative II (No Sale)

This alternative would remove the entire area of the Proposal for Sales 186, 195, and 202 from leasing for a sale.

D.3. Alternative III (Barrow Subsistence Whale Deferral)

This alternative was developed by the MMS in response to comments received in Barrow. This deferral was developed as a potential way to reduce conflicts between bowhead whale subsistence-hunter and offshore oil and gas operations and was based on bowhead whale-strike data provided by the AEWC. This alternative would offer for leasing all of the area described for Alternative I except for a subarea located in the western portion of the proposed sale area. Alternative III would offer 1,851 whole or partial blocks, comprising 9,632,000 acres (about 3,898,000 hectares). The areas that would be removed by the Barrow Subsistence Whale Deferral (see Map 2) consist of 26 whole or partial blocks, approximately 138,000 acres, about 1% of the Alternative I area. This option is being analyzed to estimate potential protection of Barrow subsistence-use zones and wildlife areas, particularly comprising an area in which whales have been taken (based on known whale-strike data). This option analyzes whether the deferral would provide increased protection to bowhead whales from potential noise and disturbance from exploration or development and production activities. The majority of the bowhead whale subsistence-hunting area near Barrow is in an area of the Chukchi Sea, which was already removed from leasing consideration in the proposed final 5-Year Offshore Oil and Gas Leasing Program for 2002-2007.

D.4. Alternative IV (Nuiqsut Subsistence Whale Deferral)

This alternative would offer for leasing all of the area described for Alternative I except for a subarea located off of Cross Island. Alternative IV would offer 1,847 whole or partial blocks, comprising 9,608,000 acres (about 3,888,000 hectares). The areas that would be removed by the Nuiqsut Subsistence Whale Deferral (see Map 2) consist of 30 whole or partial blocks, approximately 162,000 acres, about 2 % of the Alternative I area. This option is being analyzed to assess the effectiveness of potential protection of Nuiqsut subsistence-use zones and wildlife areas where whales have been taken (based on known whale-strike data). Requests for such possible protection were made by the AEWC, the Native Village of Nuiqsut, and the NSB.

D.5. Alternative V (Kaktovik Subsistence Whale Deferral)

This alternative would offer for leasing all of the area described for Alternative I except for a subarea located off of Barter Island. Alternative V would offer 1,849 whole or partial blocks comprising 9,649,000 acres (about 3,905,000 hectares). The area that would be removed by the Kaktovik Subsistence Whale Deferral (see Map 2) consists of 28 whole or partial blocks, approximately 121,000 acres, about 1% of the Alternative I area. This area is being considered for deferral in response to a request by the Native Village of Kaktovik because of the potential disturbance to Kaktovik's traditional known subsistence-whaling areas. The area was delineated using whale-strike maps provided by the AEWC.

D.6. Alternative VI (Eastern Deferral)

This alternative would offer for leasing all of the area described for Alternative I except for a subarea located east of Kaktovik. Alternative VI would offer 1,817 whole or partial blocks, comprising 9,487,000 acres (about 3,839,000 hectares). The area that would be removed by the Eastern Deferral (see Map 2) consists of 60 whole or partial blocks, approximately 283,000 acres, about 3 % of the Alternative I area. It adjoins an area that the State of Alaska has deferred in recent state sales. This option evaluates the need for protection of this area as requested by the Native Village of Kaktovik, the AEWC, and the North Slope Borough regarding the possible importance of the area to bowhead whales and other general concerns about the environment there.

E. Alternatives Not Selected for Inclusion in the EIS

Four general areas in the Beaufort Sea were recommended for deferral in comments to the September 19, 2001, Call and NOI and in the October and November 2001 scoping meetings. These were areas east of Barrow, areas around and to the east of Cross Island, areas near Kaktovik, and areas off the Arctic National Wildlife Refuge the deferrals analyzed in the draft EIS (see Section D of this Scoping Report) respond to some of the specific deferral recommendations. This section responds to the balance of the deferral recommendations. In the following, we first discuss areas recommended for deferral and our conclusions regarding those deferrals for specific parts of the Beaufort Sea. Then we look at other considerations relevant to these recommendations.

Finally, we provide the rationale for our conclusions, on which recommended deferrals are analyzed in the EIS and which are scoped out.

E.1. Areas from Barrow East to Harrison Bay

As indicated in Section B of Appendix E, in written comments, the State of Alaska supports all areas deferred from past sales, the Mayor of the North Slope Borough and the Sierra Club et al., recommended that such deferrals be removed permanently from leasing in the planning area. The Mayor also recommended that the spring-lead system and eastern Beaufort Sea should be deferred from all Beaufort Sea sales in the 2002-07 offshore leasing program. The AEWC recommended that areas used for the bowhead whale subsistence hunt be removed permanently from any future consideration for OCS leasing. Phillips Alaska Exploration opposed discretionary deferrals and arbitrary exclusions, Shell Oil supported leasing the entire nearshore area out to about 15 miles, and BPXA endorsed the sale schedule but did not comment on specific areas of the Beaufort Sea. In verbal comments at the Barrow meeting with the NSB and AEWC, those who spoke wanted MMS to permanently remove from leasing important subsistence-use areas, such as the spring-lead system and areas that might be used by bowhead whales for feeding. In the November meetings, the AEWC provided maps of potential deferral areas that were developed by the Barrow and Nuiqsut Whaling Captains, and ICAS stated their general opposition to all OCS drilling in the Beaufort Sea.

Although it is not the deferral area included in the Barrow Whaling Captains map, we are analyzing the Barrow Subsistence Whaling Deferral on the western edge of the planning area that, although much smaller (26 versus 588 whole or partial blocks), is based on whale-strike data provided by the AEWC. Also, in response to requests by Barrow residents, the NSB, and the AEWC, the Secretary removed other areas. Specifically, in her decision on the 5-Year proposed final program, she removed from leasing consideration portions of the subsistence-use area/spring-lead system to the west of this deferral area in the westernmost part of the Beaufort Sea Planning Area, and the subsistence-use area/spring-lead system in the Chukchi Sea.

Preliminary oil-field analysis of the Beaufort Sea Planning Area indicates that the 588 whole or partial blocks depicted as a candidate for deferral on the map submitted by the AEWC would reduce, by an estimated 18%, the opportunity of discovering and developing an economic oil field, if Alternative I were chosen for one of the three Beaufort Sea sales covered by this EIS. This compares to an estimated reduction of about 1% for the Barrow Subsistence Whaling Deferral.

E.2. Areas Around and East of Cross Island

In written scoping comments (see Section B.1 of Appendix E) applicable to Nuiqsut subsistence whaling, in addition to what appears for Barrow, the State of Alaska recommended that MMS apply a Cross Island Stipulation (No siting of Permanent Facilities within 10 Miles of Cross Island). The Mayor of the NSB believed this 10-mile distance is arbitrary and too small, and the area should be expanded to cover various aspects of the Nuiqsut traditional bowhead whale harvest and expanded more to the east to prevent the potential for whales to deflect due to production noise. The people of Nuiqsut want the Cross Island area permanently dropped from leasing consideration.

Although it is not the deferral recommended by the Nuiqsut Whaling Captains, we do include analysis of a smaller Nuiqsut Subsistence Whale Deferral (30 versus 94 whole and partial blocks) that is based on whale-strike data provided by the AEWC. This deferral option does include some blocks to the east of the 10-mile radius. We also analyze two versions of the no surface occupancy stipulation for Cross Island, one for seaward portions of the 10-mile radius area and one for shoreward portions. Furthermore, access to tracts in the vicinity of Cross Island may be needed, because the State has leased tracts in the adjacent State waters. Should oil be discovered on these State tracts, leasing of the adjacent Federal tracts would prevent drainage of Federal oil.

Regarding production noise from permanent industrial facilities on the OCS, companies will be required to demonstrate to the National Marine Fisheries Service that any such proposed facilities will be in compliance with the Marine Mammal Protection Act and Endangered Species Act as they seek to obtain incidental harassment authorizations and avoid conflicts with subsistence activities.

The 94 whole or partial blocks depicted as a candidate for deferral on the map developed by the Nuiqsut Whaling Captains would reduce, by an estimated 19%, the opportunity of discovering and developing an economic oil field. This compares to an estimated reduction of about 2% for the Nuiqsut Subsistence Whaling Deferral.

E.3. Areas Offshore from the Arctic National Wildlife Refuge

In scoping comments for this EIS, the Mayor of the NSB said that the eastern Beaufort Sea should be deferred from all three sales in the 2002-2007 leasing program. In comments on the 5-year offshore leasing program, the Mayor of the City of Kaktovik expressed a preference for onshore development, recommended that the area off of the Arctic National Wildlife Refuge be excluded from leasing until the Refuge is opened for development, and that all OCS blocks within 50 miles of the city be excluded. Citing these comments from Kaktovik, the Sierra Club et al. said in their scoping comments for this EIS that they supported the City of Kaktovik's request for a deferral area offshore from the Canning River to the Canadian border. This area includes 173 whole or partial blocks. Deferring it would reduce, by an estimated 23%, the opportunity of discovering and developing an economic oil field. The deferrals in Alternatives V (Kaktovik Subsistence Whaling Deferral) and VI (Eastern Deferral) cover 88 of these same blocks and run offshore of about 60% of the coastline of the Arctic National Wildlife Refuge. The selection of Alternatives V or VI would reduce (by an estimated 3% each) the opportunity of discovering and developing an economic oil field.

Although no prohibition on offshore leasing is included in the statutes governing the Arctic National Wildlife Refuge, its Comprehensive Management Plan restricts the use of the Refuge for infrastructure to support any offshore development. Also, any OCS activity or infrastructure (including pipelines to shore) would not be approved without thorough technical and environmental reviews and would have to meet the requirements of the Marine Mammals Protection Act, the Endangered Species Act, and other Federal and State statutes that help protect the natural resources of the area and environment.

The Kaktovik Whaling Captains did not submit a map but indicated that they wanted the area known as the "Barter Island" deferral from Sales 124 and 144 as a deferral for these three sales. The northern part of the "Barter Island" deferral from OCS Sale 144 is excluded from the proposed final 5-year offshore program. Alternative V, the Kaktovik Subsistence Whale Deferral, includes the Sale 144 deferral area plus a few extra blocks on the west side to more fully cover the area where AEWC data show whale strikes were made.

E.4. Other Considerations Relevant to Requests for Deferrals Off Barrow, Cross Island, and the Arctic National Wildlife Refuge

The five stipulations described (Section F) in Appendix E are included as part of all alternatives for Sales 186, 195, and 202. These are mitigating measures that will help protect the bowhead whale. The first four stipulations provide for specific protections, and the fifth is a mechanism to address unresolved conflicts between the oil and gas industry and subsistence activities. This mechanism has proven to be effective in protecting the whale hunt while allowing oil and gas activity to proceed. The mechanism can apply to whatever unreasonable subsistence-related conflicts are not resolved by other means. We also are including a possible addition to a notice of Information to Lessees (ITL 7 Information on the Availability of Bowhead Whales for Subsistence-Hunting Activities) indicating that for development plans, lessees are encouraged to consider noise-abatement methods if needed to reduce activity noise that may occur during and in the vicinity of the migration.

E.5. Rationale for Conclusions on These Three Recommended Deferrals

A primary objective of the OCS Lands Act is to make lands available for oil and gas leasing in an environmentally acceptable manner, taking into consideration protection of the marine, coastal, and human environments. An objective we undertake to meet NEPA requirements is to write an EIS that is as straightforward and as easy to understand as possible, given the inherent difficulty in estimating uncertain potential environmental effects of uncertain potential exploration and development activities based on projections of uncertain potential leasing results of planned future sales. Given the four deferral alternatives already included for analysis, these three deferral options would contribute little in the way of additional analysis to an EIS that must cover an already complicated set of issues.

We consider that the Barrow, Nuiqsut, and Kaktovik Subsistence Whaling Deferral alternatives, when combined with the other mitigating measures (stipulations and ITL's) to be analyzed in the EIS, would provide about the same level of protection of the environment as the preceding three recommended deferral areas, but they would allow at least some oil and gas exploration and development to proceed. Regarding the Arctic National Wildlife Refuge, we believe that the merits of including such a deferral option are in large part covered by analysis of Alternatives V and VI.

Furthermore, the analyses of six alternatives (proposal, no action, and four deferral alternatives), and the mitigation measures cited above for the bowhead whale subsistence hunting and other natural resources possibly affected by offshore exploration and development, meet NEPA requirements and provide alternatives that achieve the objectives of the OCS Lands Act.

F. Mitigation Measures

F.1. Proposed Mitigation Measures to be Evaluated in the EIS

The following mitigation measures (stipulations and Information to Lessees [ITLs]) will be considered as part of all alternatives for the Beaufort Sea multiple-sale EIS process (a copy of proposed Beaufort Sea multiple-sale stipulations and ITLs is attached [Attachment 2]). These measures were analyzed as part of the proposal in Sale 170, expanded and modified during Section 19 consultation, and subsequently adopted. Extensive consultation with affected groups, including the State, the NSB, AEWC, the villages of Nuiqsut and Kaktovik, industry, the Alaska Oil and Gas Association, and the National Marine Fisheries Service resulted in adoption of innovative mitigation and protection stipulations to ensure consultation and cooperation during exploration and development and production activities, for bowhead whale monitoring activities, and for protection of subsistence whaling and other activities. The State of Alaska, the NSB, the Villages of Nuiqsut and Kaktovik, and others recommended in their comments on the Call and through scoping that all measures adopted for Sale 170 be adopted for the proposed Beaufort Sea multiple-sale EIS.

F.1.a Stipulations Included in the Proposed Action

The following stipulations are considered part of all alternatives.
- No. 1 Protection of Biological Resources
- No. 2 Orientation Program
- No. 3 Transportation of Hydrocarbons
- No. 4 Industry Site-Specific Bowhead Whale-Monitoring Program
- No. 5 Subsistence Whaling and Other Subsistence-Harvesting Activities

No.1 Protection of Biological Resources: If biological populations or habitats that may require additional protection are identified in the lease area by the Regional Supervisor, Field Operations (RS/FO), the RS/FO may require the lessee to conduct biological surveys to determine the extent and composition of such biological populations or habitats. Based on any surveys that the RS/FO may require of the lessee or on other information available to the RS/FO on special biological resources, the RS/FO may require the lessee to modify operations to ensure that significant biological populations or habitats deserving protection are not adversely affected.

No. 2 Orientation Program: The lessee shall include in any exploration or development and production plans submitted under 30 CFR 250.33 and 250.34 a proposed orientation program for all personnel involved in exploration or development and production activities (including personnel of the lessee's agents, contractors, and subcontractors) for review and approval by the RS/FO. The program shall be designed in sufficient detail to inform individuals working on the project of specific types of environmental, social, and cultural concerns, including subsistence, that relate to the sale and adjacent areas.

No. 3 Transportation of Hydrocarbons: This measure requires the use of pipelines: (a) if pipeline rights-of-way can be determined and obtained; (b) if laying such pipelines is technologically feasible and environmentally preferable; and (c) if, in the opinion of the lessor, pipelines can be laid without net social loss, taking into account any incremental costs of pipelines over alternative methods of transportation and any incremental benefits in the form of increased environmental protection or reduced multiple-use conflicts.

No. 4 Industry Site-Specific Bowhead Whale-Monitoring Program: This stipulation mandates that lessees conduct a site-specific monitoring program during exploratory drilling activities, including seismic activities, to determine when bowhead whales are present in the vicinity of lease operations and the extent of behavioral effects on bowhead whales due to these activities. The stipulation requires a peer review of monitoring plans and the resulting draft reports. The monitoring plan must include provisions for recording and reporting information on sightings of other marine mammals and must provide an opportunity for an AEWC or NSB representative to participate in the monitoring program. No monitoring program will be required if the RS/FO, in consultation with the NSB and the AEWC, determines that a monitoring program is not necessary based on the size, timing, duration, and scope of the proposed operations.

No. 5 Subsistence Whaling and Other Subsistence-Harvesting Activities: This stipulation mandates that all exploration and development and production operations shall be conducted in a manner that prevents unreasonable conflicts between the oil and gas industry and all subsistence activities, particularly the subsistence bowhead whale hunt. It provides a mechanism to address unresolved conflicts between the oil and gas industry and subsistence activities. This stipulation also requires the lessee to show in its exploration or development and production plan how its activities, in combination with other activities in the area, will be scheduled and located to prevent unreasonable conflicts with subsistence areas. The protection provided by this stipulation could reduce potential conflicts between potential subsistence activities and offshore oil and gas operations and provide protection as an option in lieu of the subsistence deferral alternatives.

F.1.b Stipulations to be Evaluated in the EIS

MMS will evaluate the inclusion of other stipulations that will be developed during the EIS process.

This includes two stipulations (Stipulation 6a and 6b) regarding a No Siting of Permanent Facilities in the Vicinity of Cross Island provision. These potential stipulations may reduce effects. They will be evaluated as mitigation and as an option to the aforementioned deferral alternatives.

Sale 170 included a stipulation for No Siting of Permanent Facilities in the Vicinity of Cross Island, which is not included as part of the committed stipulation package at this time. that ITL has been divided into two parts, 6A and 6B. The EIS will develop and evaluate a similar stipulation to reduce potential impacts by potentially limiting permanent facilities in the area. Such a stipulation may reduce potential conflicts between proposed oil and gas operations and subsistence activities. The State of Alaska, the NSB, the Villages of Nuiqsut and Kaktovik, and others recommended its adoption in responses to the Call for Information. The NSB and AEWC also proposed the Nuiqsut Deferral Alternative. In response to similar comments, the MMS also developed the Nuiqsut Subsistence Whale Deferral Alternative for evaluation in the EIS. While the issue and concerns being addressed by these options are the same, the aerial extent covered by each option is different. All three of these options are being evaluated in the EIS as a means of reducing potential effects to subsistence activities. The decision about the best option(s) will be made later in the process.

F.1.c Information to Lessees Included in the Proposed Action

Items 1 through 16 apply to OCS activities in the Beaufort Sea area and are considered part of the all alternatives, including the proposed action. Sale 170 had 21 ITL clauses. Five of them were outdated or superceded by regulations. These 16 ITL clauses provide mitigation for offshore oil and gas activities. We also are considering a possible addition to a notice of Information to Lessees (ITL 7 Information on the Availability of Bowhead Whales for Subsistence-Hunting Activities) indicating that for development plans, lessees are encouraged to consider noise abatement methods if needed to reduce activity noise that may occur during and in the vicinity of the migration.

No. 1 – Information on Community Participation in Operations Planning
No. 2 – Information on Kaktovikmiut Guide *In this Place*

No. 3 – Information on Nuiqsutmiut Paper
No. 4 – Information on Bird and Marine Mammal Protection
No. 5 – Information to Lessees on River Deltas
No. 6 – Information on Endangered Whales and the MMS Monitoring Program
No. 7 – The Availability of Bowhead Whales for Subsistence-Hunting Activities
No. 8 – Information on High-Resolution Geological and Geophysical Survey Activity
No. 9 – Information on Polar Bear Interaction
No. 10 – Information on the Spectacled Eider and the Steller's Eider
No. 11 – Information on Sensitive Areas to be Considered in Oil-Spill-Contingency Plans
No. 12 – Information on Coastal Zone Management
No. 13 – Information on Navigational Safety
No. 14 – Information on Offshore Pipelines
No. 15 – Information on Discharge of Produced Waters
No. 16 – Information on Use of Existing Pads and Islands

No. 1 – Information on Community Participation in Operations Planning: This ITL encourages lessees to bring residents on the North Slope communities into their planning process. Local communities often have the best understanding of how oil and gas activities can be safely conducted in and around their area without harming the environment or interfering with community activities. Community representation on management teams that develop plans of operation and oil-spill-contingency plans that involve local community residents in the earliest stages of the planning process for proposed oil and gas activities can be beneficial to the industry.

No. 2 – Information on Kaktovikmiut Guide *In This Place*: the people of Kaktovik, the Kaktovikmiut, have compiled *A Guide for Those Wishing to Work in the Country of the Kaktovikmiut*. The guide's intent, in part, is to provide information that may promote a better understanding of their concerns. Lessees are encouraged to obtain copies of the guide and to incorporate it into their Orientation Program to assist in fostering sensitivity and understanding of personnel to community values, customs, and lifestyles in areas in which they will be operating.

No. 3 – Information on Nuiqsutmiut Paper: the people of Nuiqsut, the Nuiqsutmiut, have compiled a paper that provides information that may promote a better understanding of their concerns. Lessees are encouraged to obtain copies of this guide and to incorporate it into Orientation Programs to assist in fostering understanding and sensitivity to community values, customs, and lifestyles in areas in which they will be operating.

No. 4 – Information on Bird and Marine Mammal Protection: This ITL advises lessees that during the conduct of all activities related to leases issued as a result of this sale, the lessee and its agents, contractors, and subcontractors will be subject to the following laws, among others, the provisions of the Marine Mammal Protection Act (MMPA) of 1972, as amended (16 U.S.C. 1361 et seq.); the Endangered Species Act (ESA), as amended (16 U.S.C. 1531 et seq.); and applicable International Treaties.

No. 5 – Information to Lessees on River Deltas: Lessees are advised that certain river deltas of the Beaufort Sea coastal plain (such as the Kongakut, Canning, and Colville) have been identified by the FWS as special habitats for bird-nesting and fish-overwintering areas, as well as other forms of wildlife. Shore-based facilities in these river deltas may be prohibited by the permitting agency.

No. 6 – Information on Endangered Whales and MMS Monitoring Program: This ITL advises lessees that the MMS intends to continue its areawide endangered whale-monitoring program in the Beaufort Sea during exploration activities. The program will gather information on whale distribution and abundance patterns and will provide additional assistance to determine the extent, if any, of adverse effects to the species.

No. 7– The Availability of Bowhead Whales for Subsistence-Hunting Activities: Lessees are advised that the NMFS issues regulations for incidental take of marine mammals, including bowhead whales. Incidental-take regulations are promulgated only upon request, and the NMFS must be in receipt of a petition prior to initiating the regulatory process. Incidental takes of bowhead whales are allowed only if a Letter of Authorization (LOA) is obtained from the NMFS pursuant to the regulations in effect at the time. An LOA must be requested annually. In issuing an LOA, the NMFS must determine that proposed activities will not have an unmitigable adverse effect on the availability of the bowhead whale to meet subsistence needs by causing whales to abandon or avoid hunting areas, directly displacing subsistence users, or placing physical barriers between whales and subsistence users.

No. 8 – Information on High Resolution Geological and Geophysical Survey Activity: This ITL advises lessees of the potential effects of geological and geophysical (G&G) activity to bowhead whales and subsistence hunting activities, and reminds lessees of the specifics of the bowhead whale-monitoring program. This ITL also informs lessees that MMS intends to treat prelease G&G activities in a manner similar to the post lease G&G activities. The MMS may impose restrictions (including the timing of operations relative to open water) and other requirements (such as having a locally approved coordinator on board) on G&G surveys to minimize unreasonable conflicts between the G&G survey and subsistence whaling activities. Lessees will coordinate any proposed G&G activity with potentially affected subsistence communities, the NSB, and the AEWC to identify potential conflicts and develop plans to avoid these conflicts.

No. 9 – Information on Polar Bear Interaction: Lessees are advised that polar bears may be present in the area of operations, particularly during the solid-ice period. Lessees should conduct their activities in a manner that will limit potential encounters and interaction between lease operations and polar bears, particularly during the solid-ice period. Lessees should conduct their activities in a manner that will limit potential encounters and interaction between lease operations and polar bears. Lessees need to contact the FWS regarding proposed operations and actions that might be taken to minimize interactions with polar bears.

No. 10 – Information on Spectacled Eider and Steller's Eider: Lessees are advised that the spectacled eider (*Somateria fischeri*) and the Steller's eider (*Polysticta stelleri*) are listed as threatened endangered species by the FWS and are protected by the ESA of 1973, as amended, 16 U.S.C. 1531 et seq.

No. 11 – Information on Sensitive Areas to be Considered in the Oil-Spill Contingency Plans: Lessees are advised that certain areas are especially valuable for their concentrations of marine birds, marine mammals, fishes, or other biological resources or cultural resources and should be considered when developing oil-spill-contingency plans.

No. 12 – Information on Coastal Zone Management: Lessees are advised that the State of Alaska will review OCS plans through the review process for consistency with the Alaska Coastal Management Program. Oil-spill-contingency plans will be reviewed for compliance with State standards, the use of best available and safest technologies, and with State and regional contingency plans on a case-by-case basis.

No. 13 – Information on Navigational Safety: Operations on some of the blocks offered for lease may be restricted by designation of fairways, precautionary zones, Anchorage, safety zones, or traffic-separation schemes established by the USCG pursuant to the Ports and Waterways Safety Act (33 U.S.C. 1221 et seq.), as amended.

No. 14 – Information on Offshore Pipelines: This ITL advises lessees that the Department of the Interior and the Department of Transportation have entered into a Memorandum of Understanding, dated December 10, 1996, concerning the design, installation, operation, inspection, and maintenance of offshore pipelines. Bidders should consult both departments for regulations applicable to offshore pipelines.

No. 15 – Information on Discharge of Produced Waters: This ITL advises lessees that the State of Alaska prohibits discharges of produced waters on State tracts within the ten-meter depth contour. It informs lessees that discharges of produced waters into marine waters are subject to conditions of NPDES permits issued by the USEPA, and may also include a zero-discharge requirement on Federal tracts within the 10-meter depth contour.

No. 16 – Information on Use of Existing Pads and Islands: This ITL advises lessees that during the review and approval process for exploration and development and production plans, MMS will encourage lessees to use existing pads and islands wherever feasible.

F.1.d Mitigating Measures Not Recommended for Analysis in the EIS

There are no additional mitigating measures identified by commenters to be considered for analysis in the EIS during scoping.

APPENDIX F

EXPLORATION AND DEVELOPMENT SCENARIOS

Contents of Appendix F

EXPLORATION AND DEVELOPMENT SCENARIOS

Scenarios are conceptual views of the future. In this document, we offer scenarios regarding the timing and extent of future petroleum activities in the Beaufort Sea. The scenarios are based on economic factors, industry trends, and a large dose of professional judgment. The scenarios described here are plausible views of the future, although they project more activities than have occurred in the past in the Beaufort OCS.

Future activities primarily are scaled to assumptions of anticipated oil production. Future oil production will depend on many factors, the most important of which are access to prime areas for exploration, industry spending for leasing and exploration, and oil prices. Although seven lease sales have been held in the Beaufort Sea OCS since 1979, only a small fraction of the tracts offered (10,280 tracts) were leased by industry (692 leases). Thirty exploration wells tested 20 prospects and made 11 discoveries classified as “capable of producing in paying quantities.” However, only one field including Federal acreage (Northstar) has begun production. A summary of historical OCS leasing in the Beaufort Sea is shown in Figure III.A.2 of the EIS.

Although oil production from the Beaufort OCS has fallen short of initial expectations, this offshore province is still considered as one of the most prospective areas in the U.S. Proven geologic plays extend offshore from some of the largest fields in North America on Alaska’s North Slope (Figure III.A.1 of the EIS). The current MMS petroleum assessment indicates that recoverable oil resources could range from 3.6-11.8 billion barrels, of which 1.7-2.3 billion barrels could be economically viable at prices between $18 and $30 per barrel. Most government and industry analysts agree that this province could hold oil fields comparable in size to any frontier area in the world. Past exploration efforts have only partially tested the potential of the Beaufort shelf.

The economic potential of the Beaufort OCS has not yet been realized, because petroleum activities face a number of hurdles. These hurdles, outlined in the following, generally are not accounted for in resource-assessment models, which assume the entire area is available for exploration and funding is not a consideration. Any of the hurdles could stop the process of converting undiscovered resources to producing reserves. Because environmental and political hurdles are especially difficult to overcome in Alaska, it is important to recognize that estimates of anticipated production, and consequent effects, are likely to be overstated in environmental impact statements.

Leasing hurdles

- A lease sale is held (lease sales often are postponed).
- Industry has access to high-potential tracts (prime areas often are placed off-limits in deferrals).
- The tracts containing oil/gas resources are leased (only a small fraction of the offered tracts are leased).

Exploration hurdles

- Companies must drill to test for oil/gas pools (most leases are never drilled).
- Oil/gas pools are present in the prospects tested (most exploration wells are dry holes).
- Discoveries are large enough for commercial development (most discoveries are too small or costly).

Economic hurdles

- Oil and gas prices support commercial development (costs are high and future prices are uncertain).
- Technology is adequate for project location (new technologies may be required).
- Project meets the company’s investment criteria (most companies have other worldwide opportunities).

Legal hurdles

- Necessary permits are approved in a timely manner (permitting delays are common).
- Environmental mitigation could impact project economics (mitigation usually adds to project costs).
- Project survives legal challenges (lawsuits are common).

The MMS resource-assessment model simulates the discovery and development of offshore fields but cannot define where or when production would occur from specific tracts. Each modeling trial is likely to simulate a different development project and set of pool characteristics among the numerous geologic plays. In the real world, future offshore development depends mostly on the effort and financial commitment by industry. The steps leading from leasing to production are complicated by many factors that cannot be accurately predicted such as oil prices, technology breakthroughs, and corporate strategies. For example, higher oil prices could lead to accelerated exploration and production activities. In contrast, low oil prices could prompt industry to abandon the area without a thorough exploration effort.

F.1. Multiple-Sale Methodology

A new approach is taken in this multiple-sale EIS with respect to exploration and development (E&D) scenarios. Although there is a need to base E&D activities using anticipated production, our knowledge of the location and timing of future development activities cannot be defined with accuracy. For purposes of environmental analysis, we assume that 20% of the total available economic resources could be converted to future production for each sale in the 2002-2007 program area. This would seem to imply that after five areawide sales, all of the economic resource base would be discovered. This conclusion is not necessarily true. All of the oil resources would not be discovered in a few lease sales, because new play concepts would emerge from new discoveries. Exploration success would cause future resource estimates to be revised higher. Also, the expansion of infrastructure would lower the costs for remote, marginally uneconomic pools, perhaps allowing them to become viable.

One subjective view of future exploration and development scenarios is summarized in Table F-1. This table lists activities associated with leasing and development for a three-sale schedule in the Beaufort OCS. The table is organized around three geographic zones and three representative sale scenarios. The geographic zones are defined by proximity to the existing North Slope infrastructure and water depths (see Figure III.A.2 in the EIS), with proximity being the primary factor. Water-depth zones were picked mainly on the platform types used for development, and are broadly defined as less than 15 meters (gravel islands), 15-35 meters (bottom-founded platforms), and greater than 35 meters (subsea wells).

The percentages given for leasing and exploration are estimates of temporary activities, such as permit-related studies, seismic surveys, and exploration-well drilling. We expect that leasing would be concentrated in the Near Zone for all three sales, with activities expanding into remote areas in later sales. For example, if a total of 30 leases were issued in the first sale, 21 of these leases are expected to be in the Near Zone, 6 leases would be in the Midrange Zone, and 3 leases would be in the Far Zone. These percentages simply represent possible trends; no one can accurately foresee future leasing patterns, because each participating company could have a different strategy.

Estimates for development projects also are grouped by both sale and location. Development projects are associated with long-term disturbances and potentially higher environmental effects, because these projects last for decades. General implications for long-term activities are indicated by Table F-1. For example, in the third sale, 40% of the leasing could occur in the Near Zone, but the only commercial discovery resulting from this sale is expected to occur on tracts leased in the Far Zone. Note that areas of both shallow and medium water depths occur in remote (far) zones, and the development characteristics could be transitional between adjacent zones.

One important conclusion from this analysis is that tracts could be leased anywhere in the Beaufort Sea Planning Area in each areawide sale. Although both exploration and development are expected to be concentrated in areas near existing infrastructure (Near Zone), activities are likely to expand into more remote zones after opportunities are exhausted in easily accessible areas. This scenario does not mean that only large discoveries would be made in the Midrange and Far zones. Small discoveries could be made in remote areas, but they would be too small for commercial development. Discoveries near existing infrastructure are likely to be developed sooner, because development costs are lower. Oil pools in more remote locations must be larger to support higher development and transportation costs.

F.2. Individual Sale Scenarios

The following is a broad overview of the development scenario for the Beaufort Sea. Oil produced through offshore facilities on manmade gravel islands or bottom-founded platforms is carried by subsea pipelines buried in trenches to the onshore pipeline network connecting to the Trans-Alaska Pipeline System (TAPS). The pipeline carries oil to Valdez and marine tankers carry oil to West Coast refineries.

Associated and solution gas recovered with oil production is used as fuel for facilities or is reinjected to enhance oil recovery. After the oil reservoirs are depleted (decades), reinjected gas could be recovered through oil facilities.

Future gas production from the North Slope to outside markets would be delayed until a transportation system is constructed. Various proposals are being studied at present with no clear favorite or firm timetable for completion. Therefore, large-scale production of natural gas is not likely within the timeframe considered.

For the first Beaufort sale in the multiple-sale program, we assume the discovery/development of smaller fields in the central part of the program area. Some satellite pools could be produced by wells drilled from existing facilities, while others could require new offshore platforms. Generally, these fields would have shorter subsea pipelines through shallow water. The second sale would result in fewer, but somewhat larger, fields located outside the core area. Production from the third sale would come from a single large field in a more remote location (perhaps in deeper water). This remote field would have a longer, larger diameter offshore pipeline and require a new onshore pipeline to connect to the North Slope gathering system. A summary of the new infrastructure estimated for the three-sale program is given in Table F-2. Production profiles for all three sales are given in Figure F-1. More detailed E&D schedules are generated for each OCS sale.

One basic assumption is that the TAPS would remain operable as the regional transportation system. Studies generally have concluded that mechanical limits will be encountered at rates below 200,000 barrels per day. Throughput rates lower than 300,000 barrels per day will require modifications to the pipeline and pump stations. The lower limit for profitable operations is perhaps 400,000 barrels per day to cover the costs of administration, personnel, and continuing maintenance/repairs. Production from North Slope fields has declined since 1988 and, at the present rate of decline, the TAPS could reach an operational limit in the next 10-20 years. Production from new fields is necessary to maintain minimum flow rates through this vital transportation link now carrying approximately 20% of U.S. daily oil production. If the TAPS were to shut down, future oil production would have to rely on tanker transportation to southern markets. It is unlikely that remaining fields in northern Alaska would be able to support this transportation scenario. For purposes of analysis, we assume that the TAPS would continue to carry oil from northern Alaska.

The development scenarios assume adequate funding and effort by industry and no regulatory delays. We acknowledge that the activity schedules are more aggressive than past experience in the Beaufort OCS. If the present economic and regulatory climate continues, the assumed production and associated environmental impacts for the 2002-2007 leasing program probably are overstated.

As previously discussed, the level of activities associated with oil exploration and development is largely dependent on the market price for oil. Because of the many uncertainties associated with generating resource estimates, oil volumes are best represented by a range of possible volumes. In our resource assessment models, the benchmark prices of $18 and $30 per barrel (in 2000$) are linked to production volumes ranging between 340 million barrels and 570 million barrels for each sale. If long-term prices remain below the $18 benchmark, exploration in the Beaufort OCS is expected to be minimal and discoveries may not be developed. This low-price "exploration-only" scenario represents conditions where discoveries are too small or costly for commercial development.

Because most of the potential impacts are not very different for these two resource levels, we use a single production volume of 460 million barrels for each sale. Although the same production volumes are assumed for each sale, there would be differences in activities for the series of lease sales. The working assumption is that activities would progressively expand away from the core infrastructure area (near the existing Prudhoe Bay complex).

F.2.a. Sale 186

F.2.a(1) Exploration Activities

Exploration activity (seismic surveys and drilling) is assumed to begin in the year following Sale 186 (to be held in 2003) and continue at a rate of one exploration well per year for a total of six exploration wells (Table F-3). Our optimistic assumption is that three commercial discoveries would be made (a 50% success rate). When a discovery is made, delineation wells would use the same drilling rig and continue over a 2-year period. Two delineation wells may be drilled in a single season, as rig mobilization has already taken place. Artificial ice islands grounded on the sea bed are likely to be used as drilling platforms in shallow water (less than 10 meters deep), and nearshore operations would be supported by ice roads over the landfast ice. It is unlikely that gravel islands would be constructed to drill exploration wells in OCS waters, although older artificial islands or natural shoals could be used as a base for gravel or ice islands. Bottom-founded platforms (placed on the seafloor or on berms) could be used to drill prospects in water depths of 10-20 meters, and drillships would be used to drill prospects deeper than 20 meters. Because mobile ice conditions make ice roads unfeasible, deeper water operations would take place during the summer open-water season and would be supported by icebreakers and supply boats.

F.2.a(2) Development Activities

The development schedule (Table F-3) assumes that the first commercial discovery would be made 2 years (in 2005) after Sale 186. We assume that three new fields ranging in size from 120-220 million barrels would be discovered in alternate years. Assuming no delays in permitting, production platforms could be installed in 4 years following the discovery well. Because of their relatively small size, fields would be developed by one production platform, perhaps as a satellite with minimal onsite processing facilities. Each platform would contain one rig for development-well drilling and well-workover operations. Gravel islands would be the favored design for production facilities in water depths less than approximately 15 meters, and bottom-founded platforms would be used for production facilities in water depths to 35 meters. It is possible that some oil would be produced from extended-reach wells drilled from existing production islands. However, the volumes of oil developed by extended-reach drilling are likely to represent a minor proportion of the total production from the three new fields.

The route selection and installation of offshore pipelines would take 1-2 years and could occur either in the summer open-water season or during mid- to late winter when landfast ice has stabilized. New onshore pipeline sections would take 1 year to complete, with construction activities taking place simultaneously with the offshore pipeline installation. We assume that offshore pipelines would be trenched as a protective measure against damage by ice in all water depths less than 50 meters. At coastal landfalls, pipelines would be elevated on short, gravel causeways to protect them against shoreline processes. Onshore pipelines would be elevated 2 meters on vertical support members. The onshore pipeline corridor and shore facility construction would be concurrent with the offshore platform installation.

Because of their relatively small size, new offshore projects would use the existing infrastructure (processing facilities and pipeline-gathering systems) wherever possible. Produced oil would be gathered by existing pipeline systems within the Prudhoe Bay/Kuparuk field areas and transported to Pump Station 1 of the TAPS. We assume that Oliktok Point (using the Kuparuk or Milne Point field infrastructure), the Northstar pipeline landfall, West Dock (using the Prudhoe Bay field infrastructure), and the Badami field would be the primary landfalls.

Production rates would quickly ramp up to peak production rates for 3 years before declining. A typical field cycle from discovery to abandonment is 21 years, or approximately 5 years from discovery to startup, A 15-year production life, and 1 year for abandonment. Considering staggered discovery times of the three fields, activities resulting from Sale 186 could last until the year 2033 (Figure F-2).

F.2.b. Sale 195

F.2.b(1) Exploration Activities

Exploration seismic surveys could begin the year after the sale, and drilling is assumed to begin in the second year following Sale 195, which is scheduled for 2005 (Table F-4). We assume one or two exploration wells would be drilled in alternating years for a total of six exploration prospects tested. Our optimistic assumption is that two commercial discoveries would be made (a 33% success rate). Because of operating limitations, it is likely that only one exploration well would be drilled at each site in a year. If a discovery is made, two delineation wells would be drilled in the following season. Artificial ice islands grounded on the seabed are likely to be used as drilling platforms in water depths less than 10 meters. These operations would be supported by ice roads over the landfast-ice zone. It is unlikely that gravel islands would be constructed to drill exploration wells in OCS waters, although older artificial islands or natural shoals could be used to construct short-term exploration islands. Bottom-founded platforms of various designs could be used to drill prospects in water depths of 10-20 meters, and drillships would be used to test prospects in water depths greater than 20 meters. Because of mobile ice conditions, operations in deeper water would be supported by icebreakers and supply boats during the summer open-water season.

F.2.b(2) Development Activities

The development schedule assumes that the first commercial discovery would be made 3 years (in 2008) after Sale 195 (Table F-4). A total of two new fields ranging in size from 120-240 million barrels would be developed on tracts leased in this sale. Assuming no delays in permit approvals, production platforms could be installed in 4-5 years following the discovery well. Each field would be developed by one or two production platforms with full processing facilities. Each platform would contain one rig to drill development wells and would remain on the platform for well-workover operations. Gravel islands probably would be constructed for production facilities in water depths less than approximately 15 meters. From water depths of 15-35 meters, bottom-founded platforms would be used for production facilities and ice management strategies (spray-ice berms) would be used to control ice forces.

The installation of offshore pipelines between production platforms and onshore facilities would take 1-2 years and could occur either in the summer open-water season or during mid- to late winter when landfast ice has stabilized. New onshore pipeline sections would take 1-2 years to complete, with construction activities taking place simultaneously with the offshore pipeline installation. We assume that offshore pipelines would be trenched and buried in the seafloor as a protective measure against damage by ice in water depths less than 50 meters. At coastal landfalls, pipelines would be elevated on short gravel causeways to protect them against shoreline erosion processes. Booster stations may be required at the landfalls to maintain pressure in the onshore oil pipeline sections. Onshore, pipelines would be elevated on vertical support members. Shore facility construction would be concurrent with installation of the offshore platforms.

New offshore projects would tie into existing onshore pipeline-gathering systems at the nearest possible points. Produced oil would be gathered by existing pipeline systems to Pump Station 1 of the TAPS. We assume that landfalls would be Oliktok Point, Northstar pipeline, West Dock, and Bullen Point (A new facility to support development in the Point Thomson unit).

Production would ramp up over several years before peak production rates are achieved. The overall field life from discovery to abandonment is assumed to be 25 years, or approximately 6 years from discovery to startup, an 18-year production life, and 1 year for abandonment. Considering the staggered discovery and startup of several offshore fields, activities related to Sale 195 could last to the year 2036 (Figure F-3).

F.2.c. Sale 202

F.2.c(1) Exploration Activities

Exploration seismic surveys could begin the year after Sale 202 scheduled for 2007 (Table F-5), and drilling is assumed to begin in the third open-water season. We assume that drilling would occur at a rate of one exploration well in each 3-year period. Because of limited operating times, it is likely that only one exploration well would be drilled in a year. We assume that six prospects would be tested by drilling, resulting in the discovery of one commercial-size field (a success rate of 17%). If a discovery is made, delineation wells would be drilled at the rate of two per year. The reservoir beneath each platform site would be evaluated by two or three delineation wells. The type of exploration equipment selected would depend on water depth. Artificial ice islands grounded on the seabed are likely to be employed as drilling platforms in water depths less than 10 meters, and these operations would be supported largely by ice roads over the landfast-ice zone. It is unlikely that gravel islands would be constructed to drill exploration wells, although artificial islands or natural shoals could be used to construct short-term exploration islands. Bottom-founded platforms could be used to drill prospects in water depths of 10-20 meters. Because of mobile ice conditions, these operations would be supported by supply boats during the open-water season. For water depths greater than 20 meters, floating drilling rigs (drillships or floating platforms) would be used in the summer, and these operations would be supported by icebreakers.

F.2.c(2) Development Activities

The development schedule assumes that the discovery of one field of approximately 460 million barrels would be made 5 years (in 2012) after the sale (Table F-5). Assuming no delays in permitting, production platforms could be installed 6-7 years after the discovery well. This large field would be developed from two production platforms with processing facilities on one of the platforms. Each platform would hold one rig that would drill development wells and remain on the platform for well-workover operations. Production facilities in water depths less than 15 meters would be based on artificial gravel islands. In water depths ranging from 15-35 meters, production structures would be contained on bottom-founded platforms designed for pack-ice conditions. Active ice-management strategies (spray-ice berms) and icebreaker support ships also would be required. Oil pools in deeper water (greater than 35 meters) could be tapped by a combination of extended-reach drilled wells or subsea wells tied back to the main production platform. Subsea production technology is well-established in difficult operation areas (very deep water and extreme sea-state conditions) and represents another method of deepwater production in arctic pack-ice conditions.

Installation of offshore pipelines between production platforms and onshore facilities would take 2-4 years, considering that route surveys, trenching, and pipeline laying would take place in the relatively short open-water season. New onshore pipeline sections would take 2-4 years to complete, with construction activities taking place simultaneously with the offshore pipeline installation. We assume that offshore pipelines would be trenched as a protective measure against damage by ice in all water depths less than 50 meters. At coastal landfalls, pipelines would be elevated on short gravel causeways to protect them against shoreline erosion processes. Booster stations at the landfalls would be required to maintain pressure in the long pipeline segments. Onshore, pipelines would be elevated on vertical support members. Construction of the onshore pipeline and shore facility would be concurrent with installation of the offshore platforms.

Because this project is in a remote location, new onshore pipelines would be required to reach the existing North Slope gathering system connecting to Pump Station 1 of the TAPS. Depending on the location of the field, a new landfall would be constructed in Smith Bay (a discovery in the western Beaufort) and traverse south of Teshekpuk Lake through the National Petroleum Reserve-Alaska to the Kuparuk field infrastructure. Existing field infrastructure in the central Beaufort (Oliktok, Northstar, Endicott, Badami) could be used for oil production from deepwater areas offshore from the central Beaufort coastline. If the new field is found in the eastern Beaufort, a new landfall and facility expansion in the Point Thomson area would be constructed. Because only one remote field is expected, there would be only one landfall.

The installation of several platforms and drilling by one rig on each platform would result in a ramp-up period of several years before peak production rates are achieved. The overall field life from discovery to abandonment is 30 years, or approximately 8 years from discovery to production startup, a 20-year production life, and a 2-year abandonment period. Considering the long lead times for exploration and development at remote sites, activities resulting from Sale 202 could last until 2039 (Figure F-4).

F.3. Estimates of Muds and Cuttings for Sales 186, 195, and 202

Geologic studies indicate that exploration and delineation wells generally would test prospects from 3,000-15,000 feet in the subsurface. Based on the characteristics of geologic plays with economic resources, we assume that a representative exploration well depth is 7,000 feet. Also based on economic plays, production wells are assumed to average 10,000 feet (drilled depth), because they would include a mix of near-vertical and lateral-extended wells. We assume that one-third of the total wells would be injection wells (production:injection well ratio of 2:1). Injection wells are used for subsurface waste disposal and to optimize oil recovery (waterflood, gas-cycling, and pressure maintenance).

For these assumed drilling depths, a typical exploration well would use 425 tons (ton = 2,000 pounds) of dry mud and produce 525 tons of dry rock cuttings. We assume that 80% of the drilling mud would be recycled and, therefore, 85 tons of “spent mud” would be discharged at the exploration site. All of the cuttings (525 tons per well) would be discharged at the exploration site. A typical production well would use approximately 650 tons of dry mud and produce approximately 825 tons of rock cuttings. We assume that 80% of the drilling mud would be recycled in the multiple-well program and, therefore, 130 tons per well would be waste. Waste drilling mud, rock cuttings, and produced water would be disposed of in the subsurface by service wells on the production platform. If required, waste products could be transported to land facilities for treatment and subsurface disposal.

Spent drilling mud discharged offshore could have this typical composition:

Component	Weight %
Bentonite	6.5
Lignosulfonate	2.0
Lignite	1.4
Caustic	0.7
Lime	0.3
Barite	75.0
Drilled solids	13.0
Soda ash/Sodium Bicarbonate	0.4
Cellulose Polymer	0.7
Seawater/Freshwater	as needed
Total	100.0

Source: EPA Type 2, Lignosulfonate Mud

F.4. Changes in Activities Because of Area Deferrals

The petroleum resource assessment of the Beaufort OCS is based on geologic and engineering analysis of the entire planning area. As previously discussed, all mapped and inferred prospects are grouped into 14 geologic plays extending over broad areas of the Beaufort shelf. The results of the economic modeling indicate that only 3 or 4 of the 14 geologic plays could contain economically recoverable oil at prices ranging from $18-$30 per barrel. The play areas with economic oil resources (Appendix B, Figures B-1, B-2, B-3, and B-4) broadly define the maximum limits of the play; however, specific portions of each play area could lack any commercial potential (no petroleum traps, reservoirs are too deep, ice conditions too severe, technology is inadequate).

It is impossible to accurately define future production from specific parts of the planning area because (1) the locations of commercial-sized pools are unknown and cannot be determined without drilling; (2) future industry efforts to lease and drill specific tracts cannot be accurately predicted; and (3) commercial oil pools are not uniformly distributed over the broad play areas.

In a frontier area such as the Beaufort OCS, a simple concept often holds true: “area equals opportunity.” Removing areas from leasing certainly would eliminate the chance that commercial production would occur in that area. However, deferring one area could redirect exploration effort into remaining open areas. If excessively large areas are excluded, industry would abandon the Beaufort OCS program area and pursue other worldwide options.

Another important point is that merely leasing tracts in an OCS sale does not mean that commercial discoveries would be made on these tracts. Most tracts leased are never drilled, and many discoveries would be too small to support commercial development. Exploration activities (seismic surveys, exploration well drilling) could cause temporary disturbances, whereas long-term impacts would occur only if a commercial field is present over several decades.

Because commercial oil resources are not uniformly distributed, oil pools covered by only a few tracts could contain all of the economically recoverable reserves in the sale area. The remainder of the area could either lack the geology to produce large oil pools or have environmental conditions that would preclude commercially viability. It is important to note that this analysis reflects MMS's current data and knowledge. Industry groups could have a much different view of the oil potential in the Beaufort OCS. Future leasing patterns may reflect different industry views regarding the possible location of commercial-sized fields in the program area.

Given the inherent uncertainties for the location of future commercial discoveries, we must subjectively rank areas based on the petroleum resource assessment. This method is based primarily on the identification of geologic plays with economic potential and the projection of historical exploration trends. Table II.A-3 provides probabilities for four deferral areas under consideration. The "opportunity index" represents the probability that commercial fields would be leased, drilled, discovered, and developed in a specific deferral area.

Using the Opportunity Index for the deferral areas indicates that if all of these areas were removed from leasing, only 88% of the original petroleum potential would be available to industry. This restriction on exploration opportunity in a high-cost frontier province would affect leasing revenues and the chance for future commercial production.

Table F-1
Representation of Possible Sale-Related Activities

	Near Zone		Midrange Zone		Far Zone		
	Leasing & Exploration	Development Projects	Leasing & Exploration	Development Projects	Leasing & Exploration	Development Projects	Total Projects
Sale 1	70%	2	20%	1	10%	0	3
Sale 2	50%	1	30%	1	20%	0	2
Sale 3	40%	0	30%	0	30%	1	1
Total	53%	3	27%	2	20%	1	6

Notes:
Development zones are broadly defined by distance from the core Prudhoe Bay infrastructure and by water depths.
The Near Zone is less than 50 miles away in water depths less than 15 meters. The Midrange Zone is between 50 and 100 miles away in water depths less than 35 meters. The Far Zone is more than 100 miles away or in water depths greater than 35 meters.

Table F-2
Infrastructure Associated with the Beaufort Sea Sales 186, 195, and 202

Activity	First Sale (2003)	Second Sale (2005)	Third Sale (2007)	Sum of 3 Sales
Oil Production (BBO)	0.46	0.46	0.46	1.38
Gas Production (TCFG)	N/A	N/A	N/A	N/A
Period of Activity	2004-2034	2006-2037	2008-2039	35 years
Number of Fields	3	2	1	6
Number of Platforms	3	3	2	8
Exploration and Delineation Wells	12	12	11	35
Production Wells	69	69	68	206
Injection Wells	33	33	34	100
Offshore Pipelines (miles)	40	40	35	115
New Landfalls	0	1	1	2
New Shore Bases	0	0	1	1
New Processing Facilities	0	1	1	2

Notes:
Exploration success: Sale 186 (3 wet/6 wildcat = .50); Sale 195 (2 wet/6 wildcat = 0.33); Sale 202 (1 wet/6 wildcat = 0.17). We assume each sale will be followed by 6 wildcat tests. Assume 2-3 wet exploration-/delineation wells for each platform. Assume 1/3 of development wells are injection (2:1 production/injection). Average platform holds 34 development wells. Some wells in the third-sale scenario could be subsea wells with flowline tiebacks to production platforms in shallow water or onshore. Offshore pipelines include infield flowlines (less than 10 inches) and sales oil line (greater than 10 inches) shortest distance to landfall. Landfalls include staging areas and pump stations and are likely to be collocated with onshore processing facilities. Shore bases are temporary logistical centers associated with exploration and construction. Shore bases might be expanded to include pipeline landfalls and processing facilities associated with production operations. Abandonment begins in the last year of production and finishes the year following shutdown.

APPENDIX G

ESSENTIAL FISH HABITAT
CONSULTATION
AND
COORDINATION

List of Items in Appendix G

MMS letter dated June 20, 2002 to NMFS requesting consultation for Essential Fish Habitat (EFH) for Amendment 5 to the Fishery Management Plan for the Salmon Fisheries in the Environmental Economic Zone (EEZ) off the Coast of Alaska.

NOAA letter dated September 6, 2002 to MMS forwarding comments on the Draft EIS. EFH comment on bottom of page 3, top of page 4.

United States Department of the Interior

MINERALS MANAGEMENT SERVICE
Alaska Outer Continental Shelf Region
949 East 36th Avenue, Suite 300
Anchorage, Alaska 99508-4363

JUN 20 2002

Dr. Jim Balsiger
Regional Administrator
National Marine Fisheries Service
709 West 9th Street
P.O. Box 21668
Juneau, Alaska 99802

Dear Dr. Balsiger:

The Magnuson-Stevens Fishery Conservation and Management Act requires a Federal Agency to consult on any activity that may adversely affect essential fish habitat (EFH). The Minerals Management Service requests a programmatic consultation for EFH identified in the Environmental Assessment (EA) for Amendment 5 to the Fishery Management Plan for the Salmon Fisheries in the EEZ off the Coast of Alaska. The proposed actions we are consulting on include activities associated with leasing and exploration for oil and gas from proposed Lease Sales 186, 195 and 202 as well as exploration associated with all other existing leases in the Beaufort Sea. This programmatic consultation does not encompass the development and production activities.

Implementing regulations at 50 CFR 600.920(a)(ii) provide for consultation to be conducted programmatically when the National Marine Fisheries Service (NMFS) determines that adverse effects on EFH can be addressed for all projects at a program level. Programmatic consultations provide a mechanism to minimize or reduce the need for numerous project-specific consultations.

The Essential Fish Habitat regulations at 50 CFR 600.920(f) enable NMFS to make a finding that an existing consultation or environmental review procedure can be used to satisfy the Magnuson-Stevens Act consultation requirements.

On March 12, 2002, National Marine Fisheries Service issued a Letter of Finding allowing MMS to incorporate EFH consultations into the NEPA process. MMS may submit to NMFS a lease sale or project specific environmental impact statement (EIS) or EA, as appropriate, in lieu of a stand alone EFH assessment.

As one of the preferred methods indicated in the EFH Final Regulations published at 67 FR 2243-2383 (Federal Register, January 17, 2002), our EFH Assessment is integrated into the enclosed NEPA document (Draft EIS Beaufort Sea Multi-Sale Planning Area Oil and Gas Lease

Sale). The document includes descriptions of the nature of the programs subject to this request, an analysis of the effects of consultation-related activities on EFH and federally managed fisheries, views of the MMS regarding those effects, and identification of existing measures to mitigate potential adverse impacts.

This documentation provides the EFH assessment information as required under 50 CFR 600.920(g). If you have any questions or wish to discuss specific issues, please contact Ms. Kate Wedemeyer at 907-271-6424.

Sincerely,

John Goll

Dear Sir:

Enclosed are comments from the National Oceanic and Atmospheric Administration (NOAA) on the Outer Continental Shelf Oil and Gas Lease Sales 186, 195, and 2002 in the Beaufort Sea, Alaska. We hope our comments will assist you. Thank you for giving us an opportunity to review the document.

Sincerely,

for/ James P. Burgess, III

MEMORANDUM FOR: Steven Kokkinakis
Office of Strategic Planning

FROM: James W. Balsiger
Administrator, Alaska Region

SUBJECT: DEIS for Beaufort Sea Planning Area: Comments

The Alaska Region has reviewed the June 2002 Draft Environmental Impact Statement (DEIS) prepared by the Minerals Management Service (MMS) Alaska Outer Continental Shelf Region for Lease Sales 186, 195, and 202 in the Beaufort Sea. Please refer any questions to Brad Smith or Jeanne Hanson in our Anchorage office at (907) 271-5006.

General Comments

Seven (7) previous oil and gas lease sales have occurred in this area. Past sales have resulted in the drilling of 30 exploration wells. One development and production facility has been approved and is now operational (Northstar). The Minerals Management Service's proposed action (also described here as Alternative I) consists of offering 1,877 whole or partial blocks for lease, covering 9,770,000 acres of the Beaufort Sea planning area off Alaska. These blocks would be offered through three (3)individual sales which would occur sequentially between 2003 and 2007. Water depths in the sale area range up to 120 feet. Resource estimates indicate the range of potential oil here to be between 340 and 570 million barrels per sale. The DEIS projects 23 exploration and delineation wells would be drilled for these lease sales. The DEIS assumes a total of six new fields would be developed under these sales.

The DEIS offers five (5) additional alternatives; the no action alternative and four (4) alternative deferral areas. While it is not clear whether the DEIS intends for these alternatives to be mutually exclusive, we are recommending the adoption of Alternatives III, IV, V, and VI. These alternatives present small, but potentially valuable, improvements from the proposed action. Alternative III would reduce potential conflicts between bowhead whale subsistence hunters and offshore oil and gas operations by removing an area of 138,000 acres in waters east of the Point Barrow (one percent of the sale area). The deferral area is used by bowhead whales for migration and possibly feeding, and is within the traditional hunting areas of the village of Barrow. The MMS projects this alternative(and the others)would reduce potential effects to subsistence harvest patterns when compared to the proposed plan. While exploratory activities adjacent to the deferral area would continue and may present many of the same impacts expected in the proposed plan, Alternative III offers meaningful benefit to the protection of fish and wildlife and to locally important socio-cultural values (subsistence). We believe support for this alternative is justified. The actual area proposed for this (and all) deferrals may not fully represent the area in which bowhead whales are traditionally hunted, or in which disturbance to these whales may impact subsistence hunting. The recommendations of the AEWC and the North Slope Borough should be considered in refining the boundaries for these deferrals.

Alternative IV would reduce potential conflicts between bowhead whale subsistence hunters and offshore oil and gas operations by removing an area of 200,000 acres in waters near Cross Island (two percent of the sale area). The deferral area is used by bowhead whales for migration and possibly feeding, and is within the traditional hunting areas of the village of Nuiqsut.

Alternatives V and VI would reduce potential conflicts between bowhead whale subsistence hunters and offshore oil and gas operations by removing an area of 400,000 acres in waters north and east of the Kaktovik (four percent of the sale area). The deferral area is used by bowhead whales for migration and feeding, and is within the traditional hunting areas of the village of Kaktovik.

We remain concerned over the individual and cumulative effects of oil and gas activity on the Western Arctic population of bowhead whales. The MMS has responded to these concerns in its environmental studies program; researching many issues and providing decision makers with important data. NMFS, through the Marine Mammal Protection Act, has required comprehensive monitoring of oil and gas activities which result in the incidental take by harassment of bowhead whales and other marine mammals. The issue of industrial noise and its impact on marine mammals, especially bowhead whales, remains a subject of debate and concern. Traditional Native experience has found bowhead whales react strongly to such noise, avoiding seismic sources at distances up to 35 miles. However, research into this matter has provided data which do not suggest avoidance reactions are strong enough to yield population-level impacts to bowheads. Despite problematical limitations in these studies and their relatively brief duration, we feel they support a decision to allow OCS lease sales in the Beaufort Sea, supported by a comprehensive monitoring effort. Both MMS and NMFS (through the small take authorization program) have interests here and we are hopeful future monitoring will extend the information gathered through past research.

This is the first time MMS has written a multi-sale EIS for the Alaskan Outer Continental Shelf. NMFS believes meeting NEPA requirements through this approach is reasonable, although the Environmental Assessments for future sales in the Beaufort Sea must be written carefully and fully document individual and cumulative impacts. One of the most contentious, and potentially harmful, activities associated with leasing of the Beaufort Sea OCS has been marine geophysical (seismic) exploration. These high-energy, low-resolution surveys employ multiple vessels operating an energy source which introduces very high noise levels into the water. NMFS has worked extensively with industry, MMS, the North Slope Borough of Alaska, the Alaska Eskimo Whaling Commission, and the communities of the North Slope of Alaska in the processing of incidental take permits under the Marine Mammal Protection Act for these seismic actions. The potential for seismic activity to disturb (harass) bowhead whales has now been demonstrated through research and monitoring. Displacement of migrating bowhead whales or heightened sensitivity to noise may, in turn, adversely impact traditional subsistence use of these whales by Alaska Natives. While these effects are discussed to a degree in the DEIS (e.g., under the effects of noise on bowhead whales section), geophysical exploration through low-resolution seismic is not specifically documented as one of the actions associated with these lease sales. We believe it is necessary to provide additional detail on this activity, particularly as it concerns the cumulative effects of OCS leases in the Beaufort Sea and any impacts to marine mammals. Just as the DEIS provides projections of the number of exploration wells, production fields, and production platforms for each sale, it should also provide similar information as to geophysical seismic research.

In accordance with the procedures outlined in the May 12, 2002, letter from Rolland A. Schmitten, Director of the Office of Habitat Conservation for NMFS to Thomas A. Readinger, Associate Director for Offshore Minerals Management, MMS has provided information on Essential Fish Habitat (EFH). The DEIS never clearly states whether or not the actions proposed would adversely affect EFH. The trigger for EFH consultation is a Federal action agency's determination that an action may adversely affect EFH. If a Federal action agency determines that an action will not adversely affect EFH, no consultation is required, and the Federal action agency is not required to contact NMFS about their determination. NMFS believes that while the exploration, development and production scenarios generated by MMS are plausible, possible adverse effects to EFH should be identified on a project specific basis. Therefore, no further EFH consultation is necessary at this time. The need for additional EFH consultation should be determined as specific projects are designed.

Specific Comments

Pg I-10, I.C.2.b(1). The second paragraph here indicates the Secretary has previously removed from leasing sections of the Beaufort Sea OCS west of the Barrow deferral area (Alt. III). This represents a positive action by the MMS which responds to concerns over bowhead whales and traditional hunting practices. We believe, then, the area mentioned should be identified in Map 3 and included in the discussion of deferrals.

Pg. I-10, I.C.2.b(2). This defends the need to lease blocks near Cross Island based, apparently, on preventing adjacent State of Alaska tracts from draining oil reserves from Federal OCS areas. This matter should be adjudicated through the courts, and does not seem to be justification for leasing.

Pg.II-11. II.H.1.c. The DEIS does not adequately assess the potential impacts of additional causeways. Therefore, we would consider the DEIS deficient if the proposed activities include additional causeways.

The individual and cumulative effects of causeways on coastal fisheries has long been the focus of controversy. The debate centers on fish passage around the structures and possible adverse changes to habitat which may impact population productivity. Changes to habitat (i.e. changes in temperature and salinity regimes) have been documented to occur as a result of causeway induced deflections of currents and entrained waters away from the coast.[1]

---

[1]. Thorsteinson, L.K., L.E. Jarvela, and D.A. Hale. November 1990. Arctic Fish Habitat Use Investigations: Nearshore Studies in the Alaskan Beaufort Sea, Summer 1988. U.S. Dept. of Commerce and U.S. Dept. of Interior, OCSEAP Final Report, 71: 349-485.

Regardless of whether or not these changes have biological significance, there is implicit agreement that preserving the integrity of the warmer, brackish coastal boundary layer during summer months is crucial in sustaining the biota of the region. We consider the brackish nearshore corridor critical to the success of marine and anadromous fish stocks. In addition, freshwater flows from coastal rivers and streams are important to the creation of the brackish warm zone, and it is essential to sustain natural flows to avoid impacts.

Therefore, we believe that Stipulation No. 3, Transportation of Hydocarbons, should be modified to reflect the MMS's position regarding causeways. This would clarify that no new causeways would be constructed. Extensive causeways have many undesirable impacts on nearshore processes and resources and should be prohibited outright.

Pg.II-12. II.H.1.d. We recommend the third sentence in the second paragraph here, beginning with "Scientific studies" be replaced with the following statement: Monitoring studies of 3-D seismic exploration (6-18 airguns totaling 560-1500 c.i.) in the nearshore Beaufort Sea during 1996-1998 have demonstrated that nearly all bowhead whales will avoid an area within 20 km of an active seismic source, while deflection may begin at distances up to 35 km.

Pg. II-15. II.H.2.a. Stipulations 6a and 6b provide that permanent facilities within 10 miles of Cross Island should not preclude "reasonable subsistence access" to whales. Earlier in the DEIS we learn that noise from such facilities must comport with the small take authorization program under the MMPA. The regulations for that program require these takes "will not have an unmitigable adverse impact on the availability of the species or stock(s) for subsistence uses." We recommend that Stipulations 6a and 6b adopt this language in order to bring consistency among these efforts and to clarify intent.

Pg. III-37. III.B.4a(1). The first paragraph on this page mentions the possibility that bowhead whales may occupy the northeastern portion of the Chukchi Sea more often than previously thought, and that these whales may occur regularly along the northwestern coast during summer. Monitoring during the towing of the Steel Drilling Caisson drill rig during summer of 2002 recorded five bowhead whales off Point Barrow on July 21, further supporting these findings.

Pg. III-40. III.B.4.a(1) It is more than unfortunate the final report of the bowhead whale feeding study is not included within this discussion, or available for planning purposes. This multi-year effort represents a comprehensive research effort intended to identify and characterize the use of the eastern Beaufort Sea as feeding habitat for bowhead whales, and to place some perspective on the importance of that habitat. NMFS personnel participated in the Scientific Review Board for this work, and a draft final report on the study was released in December of 2001. We strongly encourage MMS to complete this important work and incorporate its conclusions and data into the final NEPA document.

Pg. IV-4. IV.A.1. The significance threshold described here for threatened or endangered species should be considered further. We believe it is unreasonable to limit this to effects lasting a generation or more; particularly for long-lived animals such as the bowhead whale with a life span possibly exceeding 100 years. Would an activity that displaces bowheads from a traditional feeding area for 50 years then be considered insignificant?

Pg. IV-5. IV.A.2.B. The projections are that a maximum of two drilling rigs would operate at any time under Sale 195 (and one for Sale 202). Are these estimates specific to those sales, or is this an absolute maximum? In other words, could we see two rigs drilling on Sale 195 tracts, and another drilling a Sale 202 tract?

Pg. IV-6. IV.A.2.b(1)(a). As previously stated, we recommend the final EIS present additional discussion on geophysical seismic research, in addition to the site survey seismic work described here.

Pg. IV-13. IV.A.4.a. The spill modeling assumes the oil will be similar to Alaska North Slope crude oil. How typical is this? We understand that Northstar crude is markedly different than that from the Prudhoe Bay field. Is it logical to assume offshore oil from newly developed reservoirs would be more similar to North Slope crude?

Page IV-10. IV.A.2.b(3). Information on the impacts of dredging needs to be included or referenced in this section. While suspended sediments per se have very low direct toxicity values, the composition of sediments should be tested prior to assessing the potential impacts from dredging. In Norton Sound, for example, nearshore sediments contain high background levels of mercury and other metals. Dredging activities may resuspend such materials and make them available to aquatic organisms, with resultant adverse effects.

Page IV-13. IV.A.4.a. On page IV-3, the DEIS states the analyses presented consider whether the mitigation that is proposed as part of the project can reduce or eliminate all or part of the potential adverse effects. Here, however, the analysis of large oil spills assumes there is no clean up or containment. This seems illogical, as oil spill response and preparedness are very much part of the mitigative measures directed at OCS activities.

Page IV-15. IV.A.6. This section should also include a description of dispersants and any considerations or restrictions on their use in the Beaufort Sea.

Page IV-16. IV.A.6.a. Please provide further description of the experience(s) of using the described small-vessel skimming system "successfully" in Cook Inlet amid broken ice.

Page. IV-16. IV.A.6.c. The stated response technology for a spill occurring during late fall freeze-up is to allow the spill to freeze in place, then mining the oil from the pack ice. Is there any reasonable prediction of the efficiency of this technology, or examples of its testing or actual use?

Page IV-21. IV.C.1.a(1). The DEIS states that trace metals would be added to the water by drilling muds and cuttings. It further states that the Environmental Protection Agency (EPA) prohibits the discharge of drilling muds and cuttings in less than 5 meters. Additional discussion regarding the dispersion of these pollutants and the ability to meet water quality criteria at the edge of mixing zones seemingly dismiss the possible impacts from these pollutants. What would be the impact if these pollutants from exploratory activity were re-suspended during activities such as dredging for subsea pipelines? MMS should consider putting this information in their "Information to Lessees" and encourage lessees to discharge of such materials downhole whenever possible.

Page IV-22-23. IV.C.1.a(3). This section discusses the effects of permitted discharges of produced waters. While it is noted that to date for exploration, the EPA has prohibited the discharge of formation waters into waters of less than 10 meters, the section does provide information on the maximum amount of oil and grease in produced waters over the next 21 years. The document goes on to state that if produced waters were discharged for a project, "the effect on water quality would be local, but would last over the life of the field." What would be the cumulative impacts for all the proposed exploration and development projects for all three leases? Also, what kind of impacts could be expected inside the "mixing zone"? By contrast an entire section is spent describing the probable effects of an accidental oil spill on various resources. Should an oil spill occur, presumably it would be a one time event. A discharge of production waters would occur on a consistent basis. What would this mean to resources and habitat?

Page IV-144. IV.C.11.b(3). NMFS is supportive of Stipulation 4, and believe such monitoring is necessary to fully assess the effects of OCS actions on bowhead whales. However, we feel the first sentence on this page (This stipulation helps to reduce effects to subsistence-harvest patterns and to the overall socio-cultural systems which place special value on the bowhead whale harvest and the sharing of this harvest with other members of the community) overstates the benefits of this monitoring. The statement that this stipulation is considered to be a positive action by he Native community under environmental justice should be referenced.

It is not clear why Stipulation 6 is presented in two parts, a and b. Would both apply?

Page IV-146. IV.C.11.c(1)(a). The DEIS states in the second paragraph that potential disturbances to bowhead whales from seismic operations would be limited to areas west of Cross Island, because of the provisions of (past and existing) conflict avoidance agreements. The DEIS should consider that these agreements are primarily for the protection of the subsistence hunt. These agreements often allow for seismic work to proceed once a village has reached its quota, after which the potential for seismic to disturb these whales may be very high.

Page IV-219. IV.I.2.k(1). In describing the potential effects of an oil spill on subsistence uses, this analysis very correctly states that there would be long term effects, often based in part on the perception that a marine mammal could be tainted. This analysis may be somewhat flawed in basing discussions on the results of the oil spill model, which estimates the chance of an oil spill contacting a particular environmental resource, such as Point Barrow. This approach may not fully account for seals and whales which move among these resource areas. If a seal became oiled near Cross Island, and was harvested near Barrow some time later, subsistence use of the area would certainly be affected even though no oil had contacted that resource area.

Page V-1. V. Cumulative Effects. This section seems to confine its analysis to other oil and gas projects, rather than the cumulative impacts of the lease sales when added to <u>all</u> other past, present, and foreseeable future actions.

Page V-5. V.A.7. We believe that repeated exposure of migrating bowhead whales to noise sources may be an example of synergistic impact. While whales may avoid a source by moving further offshore before resuming their normal course, and may make such avoidance movements around several sources (additive impact), there may be a point at which the whales remain offshore after exposure to multiple sources, even once the source is no longer present. Given the many potential noise sources associated with exploration, development, and production on the Beaufort Sea OCS, Natives and scientists have considered this a real possibility.

Page V-28. V.C.5.a(1)(b). The FEIS should present an expanded discussion of development and exploration within the Canadian Beaufort, particularly off the McKenzie delta, as well as vessel movement into and out of Canadian waters necessary to support activities within the Alaskan Beaufort Sea OCS. Expansion of the Canadian fleet to support U.S. development would present several concerns with respect to bowhead whales and subsistence hunting, as late season traffic in the eastern Beaufort Sea would be most likely to encounter, and harass, these whales.

APPENDIX H

FR NOTICE OF JUNE 19, 2002
COMMENTS TO DEIS
AND
LISTING OF E-MAIL

List of Items in Appendix H

Federal Register Notice of June 19, 2002

Comment Letters Received

DEIS Public Hearing Attendees

Information about E-Mail Comments Received to the Draft EIS.

DATES: The meeting will take place June 20, 2002, from 9:00 am to 4:45 pm ET, and June 21, 2002, from 8:30 am to 11:45 am ET.

ADDRESSES: Ritz-Carlton Washington, DC, 1150 22nd Street, NW., Washington, DC 20037.

PUBLIC COMMENTS: The meeting agenda will be posted at *http://www.bioethics.gov.* Written statements may be submitted by members of the public for the Council's records. Please submit statements to Ms. Diane Gianelli (tel. 202/296–4669 or e-mail info@bioethics.gov). Persons wishing to comment in person may do so during the hour set aside for this purpose beginning at 3:45 p.m. ET on Thursday, June 20, 2002. Comments will be limited to no more than five minutes per speaker or organization. Please give advance notice of such statements to Ms. Gianelli at the phone number given above and be sure to include name, affiliation, and a brief description of the topic or nature of the statement.

FOR FURTHER INFORMATION CONTACT: Diane Gianelli, 202/296–4669, or visit our website at *http://www.bioethics.gov.*

Dated: June 11, 2002.

Dean Clancy,

Executive Director, The President's Council on Bioethics.

BILLING CODE 4110–60–P

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Administration for Children and Families

[Program Announcement No. OCS–2002–10]

Request for Applications Under the Office of Community Services' Fiscal Year 2002 Community Economic Development Program

AGENCY: Office of Community Services (OCS), Administration for Children and Families Department of Health and Human Services.

ACTION: Correction and Clarification.

SUMMARY: This document clarifies and corrects the notice that was published in the **Federal Register** on Tuesday, May 28, 2002, Part IV (67 FR 37274). It corrects a telephone number and the spelling of a street name address. It clarifies the notice by removing subsection points for Criterion VI: Project Evaluation. Also, it clarifies that references to Sub-priority Areas 1.5 and 1.6 in Attachment K, "Guidelines for a Business Plan" do not apply to any Priority Areas for this announcement.

FOR FURTHER INFORMATION CONTACT: Kathren Turner at (202) 260–5683 or the OCS Operation Center at 1–800–281–9519 for referral to the appropriate contact person in OCS for programmatic questions or send an e-mail to *OCS@lcgnet.com.*

Corrections

In the **Federal Register** issue of May 28, 2002 (67 FR 37274), on page 37274, third column, remove "FOR GENERAL QUESTIONS ON THE ANNOUNCEMENT, CONTACT: Mr. Ros Relaford, Technical Assistance Manager, OCS Operations Center, Call: 1–800–281–9516, or E-mail: *OCS@lcgnet.com*" and add: "FOR GENERAL QUESTIONS ON THE ANNOUNCEMENT, CONTACT:" Mr. Ros Relaford, Technical Assistance Manager, OCS Operations Center, Call: 1–800–281–9519, or E-mail: *OCS@lcgnet.com*".

Also, in the **Federal Register** issue of May 28, 2002 (67 FR 37274), on page 37274, in the first column, under "Application Submission", *Mailing and Delivery Address*:, 4th line, in the second column, 2nd paragraph, 8th line, under *Submission Instructions*; and in the 3rd column, under "For A Copy Of Announcement, Contact:" 2nd line, remove "Fort Meyer Drive", and replace with "Fort Myer Drive".

Clarifications

In the **Federal Register** issue of May 28, 2002 (67 FR 37274), on page 37285, remove all the points under the subsections (1–4) as found under "Criterion VI; Project Evaluation"; that is column 2, end of 2nd paragraph of subsection (1), remove "(0–2 points)"; end of subsection (2), remove "(0–2 points)"; column 2, end of paragraph 1, subsection (3), removed "(0–2 points)"; and column 3, end of subsection (4), remove "(0–2 points)".

In the **Federal Register** issue of May 28, 2002 (67 FR 37274), under Attachment K, "Guidelines for a Business Plan," on page 37307, beginning of the second paragraph of the third column and ending on page 37308, end of third column, sections that reads "Applicable to Sub-priority Area 1.5 Only," "Applicable to Sub-priority Area 1.6 only", "Applicable to Sub-priority 2.1" and "e. Significant Beneficial Impact and Other Criteria," do not apply to any Priority Area in this notice.

Dated: June 9, 2002.

Clarence Carter,

Director, Office of Community Services.

[FR Doc. 02–15390 Filed 6–18–02; 8:45 am]

BILLING CODE 4184–01–M

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration

Food Advisory Committee Meeting; Cancellation

AGENCY: Food and Drug Administration, HHS.

ACTION: Notice.

SUMMARY: The Food and Drug Administration (FDA) is canceling the meeting of the Food Advisory Committee scheduled for June 20 and 21, 2002. This meeting was announced in the **Federal Register** of May 30, 2002 (67 FR 37844).

FOR FURTHER INFORMATION CONTACT: Constance J. Hardy, Center for Food Safety and Applied Nutrition (HFS–811), Food and Drug Administration, 5100 Paint Branch Pkwy., College Park, MD 20740, 301–436–1433, or FDA Advisory Committee Information Line, 1–800–741–8138 (301–443–0572 in the Washington, DC area), code 10564.

Dated: June 13, 2002.

William K. Hubbard,

Senior Associate Commissioner for Policy, Planning, and Legislation.

BILLING CODE 4160–01–S

DEPARTMENT OF THE INTERIOR

Minerals Management Service (MMS)

Outer Continental Shelf (OCS), Alaska OCS Region

AGENCY: Minerals Management Service, Interior.

ACTION: Notice of Availability of the Draft Environmental Impact Statement (EIS) for the Proposed Oil and Gas Lease Sales in the Beaufort Sea, Alaska.

SUMMARY: MMS announces the availability of the draft EIS prepared by MMS for the Proposed OCS Lease Sales 186 (2003), 195 (2005), and 202 (2007) offshore Beaufort Sea, Alaska.

DATES: Comments on the draft EIS are due September 20, 2002. Public hearings will be held in Alaska: Barrow, July 22, 2002; Nuiqsut, July 24, 2002; Kaktovik, July 26; 2002; and Anchorage, July 30, 2002.

FOR FURTHER INFORMATION CONTACT: Minerals Management Service, Alaska OCS Region, 949 East 36th Avenue, Anchorage, Alaska 99508–4363, Atttention: Mr. Paul Lowry, telephone: (907) 271–6574 or toll free 1–800–764–2627.

SUPPLEMENTARY INFORMATION: This draft EIS assesses three lease sales in the Proposed Final 2002–2007 5-Year Oil and Gas Leasing Program for the Beaufort Sea OCS Planning Area. Sale 186 is scheduled for 2003; Sale 195 for 2005; and Sale 202 for 2007. Federal Regulations (40 CFR 1502.4) suggest analyzing similar or like proposals in a single EIS. The proposal for each sale is to offer 1,877 whole or partial lease blocks in the Beaufort Sea Planning Area, covering about 9.8 million acres (3.95 million hectares) for leasing. The proposed sale area is seaward up to 60 miles offshore of the State of Alaska submerged land boundary in the Beaufort Sea. It extends from the Canadian border on the east to near Barrow, Alaska, on the west.

EIS Availability: Persons interested in reviewing the Draft EIS "OCS EIS/EA, MMS 2002–29" (Volumes I and II) can contact the MMS Alaska OCS Region. The documents are available for public inspection between the hours of 8 a.m. and 4 p.m., Monday through Friday at: Minerals Management Service, Alaska OCS Region, Resource Center, 949 East 36th Avenue, Room 330, Anchorage, Alaska 99508–4363, telephone: (907) 271–6070, or (907) 271–6621, or toll free at 1–800–764–2627. Requests may also be sent to MMS at *akwebmaster@mms.gov.* You may obtain single copies of the draft EIS, or a CD/ROM version, or the Executive Summary from the same address. The Executive Summary (MMS 2002–30) is available in English or Native Inupiat languages.

You may look at copies of the draft EIS in the following libraries:

Public Hearings Public hearings on the draft EIS will be held at the following locations on the dates and times listed:

Barrow, Alaska, Monday, July 22, 2002, Inupiat Heritage Center, Multipurpose Room, 7–9 p.m.
Nuiqsut, Alaska, Wednesday, July 24, 2002, Kisik Community Center, 7–9 p.m.
Kaktovik, Alaska, Friday, July 26, 2002, Quargi Community Center, 7–9 p.m.
Anchorage, Alaska, Tuesday, July 30, 2002, 949 East 36th Avenue, 3rd Floor 4–7 p.m.

An Inupiat translator will be available at the public hearings held in Barrow, Kaktovik, and Nuiqsut.

Oral and written comments on the draft EIS will be addressed in the final EIS. If you wish to testify at a hearing, you may register prior to the hearing to schedule a preferred time by contacting the Alaska OCS Region at the above address or Mr. Paul Lowry at (907) 271–6574 or toll free 1–800–764–2627 not later than 5 days prior to the hearing date. Every effort will be made to accommodate individuals who have not pre-registered to testify. Time limitations may make it necessary to limit the length of oral statements to 10 minutes. You may supplement an oral statement with a more complete written statement and submit it to a hearing official at the hearing or by mail until September 20, 2002. Each hearing will recess when all speakers have had an opportunity to testify. If, after the recess, there are no additional speakers, we will adjourn the hearing immediately after the recess. Written statements submitted at a hearing will be considered part of the hearing record. If you cannot attend the hearings, or if you prefer, you may submit your comments in writing to the address below.

Written Comments MMS requests interested parties to submit their written comments on this draft EIS to the Regional Director, Alaska OCS Region, Minerals Management Service, 949 East 36th Avenue, Room 308, Anchorage, Alaska 99508–4363. Our practice is to make comments, including the names and home addresses of respondents, available for public review. An individual commenter may ask that we withhold their name, home address, or both from the public record, and we will honor such a request to the extent allowable by law. If you submit comments and wish us to withhold such information, you must state so prominently at the beginning of your submission. We will not consider anonymous comments, and we will make available for inspection in their entirety all comments submitted by organizations or businesses or by individuals identifying themselves as representatives of organizations or businesses. The comment period ends on September 20, 2002.

Dated: May 29, 2002.

Thomas A. Readinger,

Associate Director for Offshore Minerals Management.

Dated: May 30, 2002.

Terrence N. Martin

Acting Director, Office of Environmental Policy and Compliance.
