## Section 5. Crude Oil and Natural Gas Resource Development

The September 2004 rotary rig count was 1,240, slightly higher than the count in August 2004 and 13 percent higher than the count in September 2003. Of the total number of rigs in operation, 1,148 were onshore and 92 were offshore. For September 2004, the number of onshore rigs was up 17 percent but the number of offshore rigs was down 16 percent from the September 2003 count. Rotary rigs drilling for natural gas as a share of total rigs stood at 87 percent in September 2004.

Total footage drilled in September 2004 was 16.0 million feet, 6 percent lower than the footage drilled in August 2004 but up 1 percent from that drilled in September 2003.

The number of exploratory and development crude oil and natural gas wells drilled during September 2004 was 2,400, down 6 percent from the number drilled in August 2004 but up 6 percent from the number drilled in

September 2003. The number of crude oil wells drilled was 471, and the number of natural gas wells was 1,929, 2 percent higher and 8 percent higher, respectively, than their September 2003 levels.

The number of dry holes drilled in September 2004 was 401, down 6 percent from the number drilled in August 2004 but up 4 percent from the number drilled in September 2003.

There were 2.1 thousand well service rigs active in September 2004, 1 percent lower than the previous month but 6 percent more than the count a year ago.

The number of seismic crews active in the 48 States onshore in September 2004 was 40, 10 more than a year earlier. The number of crews active in the 48 States offshore was 6, 3 fewer than a year earlier. Two crews were active in Alaska in September 2004, 2 more than a year ago.

Notes: - These well counts include only the original drilling of a hole intended to discover or further develop already discovered crude oil or natural gas resources. Other drilling activities, such as drilling an old well deeper, drilling of laterals from the original well, drilling of service and injection wells, and drilling for resources other than crude oil or natural gas are excluded. Due to the methodology used to estimate ultimate well counts from the available partially reported data, the counts shown on this page are frequently
revised. See notes at end of section. - Geographic coverage is the 50 States and the District of Columbia.

[^1]nearby offline features that 2 D surveys are prone to (except, of course, along the outer faces of the cube). Four dimensional (4D) reflection seismic surveying is the exact repetition of a 3D survey at two or more time intervals. The primary application of 4D is mapping the movement of fluid interfaces in producing oil and gas reservoirs.
d Includes crews with unknown survey dimension.
Notes: - A "seismic crew" is a group of people, of varying number, engaged in a seismic surveying job. - "48 States" is the United States excluding Alaska and Hawaii. - Data are reported on the first and fifteenth of each month, except January when they are reported only on the fifteenth. When semi-monthly values differ for the month, the larger of the two values is shown here. Consequently this table reflects the maximum number of crews at work at any time during the month.

## Crude Oil and Natural Gas Resource Development

## Table 5.2 Notes

Three well types are considered in the Monthly Energy Review (MER) drilling statistics: "completed for crude oil," "completed for natural gas," and "dry hole." Wells that productively encounter both crude oil and natural gas are categorized as "completed for crude oil." Both development wells and exploratory wells (new field wildcats, new pool tests, and extension tests) are included in the statistics. All other classes of wells drilled in connection with the search for producible hydrocarbons are excluded.

Prior to the March 1985 MER, drilling statistics consisted of completion data for the above types and classes of wells as reported to the American Petroleum Institute (API) during a given month. Due to time lags between the date of well completion and the date of completion reporting to the API, as-reported well completions proved to be an inaccurate indicator of drilling activity. During 1982, for example,
as-reported well completions rose, while the number of actual completions fell. Consequently, the drilling statistics published since the March 1985 MER are Energy Information Administration (EIA) estimates produced by statistically imputing well counts and footage based on the partial data available from the API. These estimates are subject to continuous revision as new data, some of which pertain to earlier months and years, become available. Additional information about the EIA estimation methodology may be found in "Estimating Well Completions," the feature article published in the March 1985 MER.

Users of the well completion and footage figures published by the Energy Information Administration (EIA) prior to August 1998 should be aware that these data have been revised. The published well completion and footage figures are produced by the Well Completion Estimation Procedure (WELCOM) based on drilling records provided under contract to the EIA. Problems in the files received by EIA necessitated revision of the historical series for well completions and footage drilled. Queries regarding this matter may be directed to William Trapmann (202-586-6408 or william.trapmann@eia.doe.gov).

[^0]:    a Rotary rigs in operation are reported weekly. Monthly data are averages of 4 - or 5 -week reporting periods, not calendar months. Multi-month data are averages of the reported data over the covered months, not averages of the weekly data. Annual data are averages over 52 or 53 weeks, not calendar years. Published data are rounded to the nearest whole number.
    b Sum of rigs drilling for crude oil, rigs drilling for natural gas, and other rigs (not shown) drilling for miscellaneous purposes, such as service wells, injection wells, and stratigraphic tests.
    c Values shown are totals.
    d See Glossary.

[^1]:    a Federal and State Jurisdiction waters of the Gulf of Mexico.
    ${ }^{b}$ All onshore.
    c In two-dimensional (2D) reflection seismic surveying both the sound source and the sound detectors (numbering up to a hundred or more per shot) are moved along a straight line. The resultant product can be thought of as a vertical sonic cross-section of the subsurface beneath the survey line. It is constructed by summing many compressional (pressure) wave reflections from the various sound source and sound detector locations at the halfway sound path points beneath each location (common depth point stacking). In three-dimensional (3D) reflection seismic surveying the sound detectors (numbering up to a thousand or more) are spread out over an area and the sound source is moved from location to location through the area. The resultant product can be thought of as a cube of common depth point stacked reflections. Advantages over 2D include the additional dimension, the fact that many more reflections are available for stacking at each point, which provides greatly improved resolution of subsurface features, and elimination of the "ghost" or "side swipe" reflections from
