Abstract

Archived specimens of seabirds are playing critical roles in many studies contrasting changes in time and space in genetics, stable isotopes, and contaminants. Seabirds are excellent marine bioindicators, representing multiple trophic levels and being especially rich at higher levels. Preserving and archiving multiple sample types from these animals caters to an increasingly broad variety of researchers. By preserving these samples, we enable present and future analyses for questions ranging from changes in contaminant levels, to the nature of populations and genetic stocks in affected areas, to other issues related to Outer Continental Shelf (OCS) activities. Having the samples to address retrospective and geographic comparative analyses is important for studying the rates and characteristics of natural and anthropogenic changes.

This project focused on an increasing interest and need for samples of preserved marine bird specimens, particularly for genetic, contaminant, and stable isotope studies. Having material available for such studies is critical, particularly material from representative time periods and geographic areas. Requests for samples of several different types have made it clear that demand exceeds supply, and that low rates of specimen influx were not meeting this demand, particularly in the documentation of recent years. By supporting a graduate assistantship to process marine bird specimens, this project stimulated such sample preservation and made it less geographically and taxonomically haphazard than in the past. During this project 872 seabirds were prepared and archived as skin, and/or skeleton, and tissue samples in the University of Alaska Museum (UAM). This was 45% more than forecast when the project began. A snowballing effect has occurred, both in the deposition of more specimens and in the level of interest in this new material. Equally important has been the graduate training opportunity that this support provided, a student opportunity with continuing commitment by the Museum. This support served as a platform from which Deborah Rocque completed her doctoral degree. Thirteen visitors to the collection have used seabird specimens for their research, and ten loans have been made to researchers worldwide studying Alaska seabirds. In sum, the project has been very successful. This success will be built upon as we continue to preserve and archive seabirds and as researchers continue to capitalize on this important and growing research resource.

Introduction

More than 100 species of Alaska birds depend on marine environments. These species occupy three trophic levels and represent a major component of the nation's marine ecosystems. These birds are vulnerable to both natural and anthropogenic changes (e.g., Outer Continental Shelf activities) and are also politically sensitive animals because they are protected by international treaties with Russia, Japan, Canada, and Mexico. Also, many are a source of food for humans. Birds have long served as environmental indicators—"canaries in the coalmine"—and specimens representing baseline conditions have been crucial for documenting both natural and anthropogenic changes. Perhaps the most widely recognized example of this was the use of historic museum egg collections to demonstrate the effects of increased concentrations of DDT on the reproduction of birds occupying higher trophic levels (e.g., Peregrine Falcons, *Falco peregrinus*). A more recent example is the use of

historic bird specimens to document the effects of runoff contaminants into marine ecosystems in California. The bottom line is that samples that temporally span change events, or at least document conditions in change and non-change areas, are crucial for comparative studies.

Providing samples to support environmental research is an increasingly important function of natural history museums. But with limited resources to apply to broad taxonomic, geographic, and scientific demands, museums do well to cover even a few areas adequately. Many of the researchers making sample requests to the University of Alaska Museum are studying questions directly relevant to the framework issues of interest to the Minerals Management Service (MMS), and this project—a partnership with MMS, through the University of Alaska Coastal Marine Institute (CMI)—has enabled marine bird samples to be actively brought in and preserved for this research community. Requests for Alaska marine bird samples vary from studies of temporal contrasts of contaminant levels and stable isotope ratios, to comparative systematic studies of population- and species-level genetics and morphology, to synoptic studies for the identification of archaeological material. This collection, although limited in its holdings, provides these researchers with a substantial percentage of the samples pertinent to their questions. It has been clear that this science would be substantially strengthened if more samples were available, and this project has enabled us to begin to meet this objective through the half-time graduate assistantship that it supported to process marine birds.

This project is distinct from other sample preservation projects, and it has begun to fill a major gap in existing sample archiving efforts. It complements existing projects and addresses an identified weakness in the preservation of specimens of higher marine organisms. Our objectives have been to preserve a substantially increased number of marine and coastal bird samples from Alaska for studies ranging from contaminants and stable isotopes to genetics and morphology, and of course to make these samples available to the research community. Alaska seabird specimens were not being archived anywhere at levels sufficient to meet the needs of this research community, and the UA Museum is in a unique position to address this need. These archived samples enable researchers to test numerous hypotheses, particularly those addressing environmental changes from events such as contaminations and other OCS activities that potentially impact Alaska's marine environments.

Methods

One of our most important goals in sample archiving is to maximize the usefulness of each individual bird to the scientific community. When possible, we preserve a combination skin/skeleton prep, two tissue samples, and stomach contents from each bird. We use no chemicals in the preparation process, except when a specimen is particularly fatty; in these cases the fat remaining after fleshing the skin is often removed with a solvent (e.g., mineral spirits). Skin and skeleton preparations are archival in quality and are expected to last for centuries. Tissue samples are placed in two, 2-mL plastic cryovials and archived at -70 °C in the Alaska Frozen Tissue Collection (AFTC). Stomach contents are preserved in isopropyl alcohol.

Results

This project had tremendous direct and indirect effects on seabird sample archiving at the University of Alaska Museum (Figure 1). It produced substantially more archived specimens than the initial projection: 600 were projected in the proposal; 872 were preserved, or 45% more than forecast. It also served as a platform of support from which doctoral student Deborah Rocque was recruited and accepted into our program (Department of Biology & Wildlife) and under which she completed much of her dissertation research [Rocque 2003]. This graduate student training opportunity has been continued by the museum. An excerpt from Dr. Rocque's dissertation research is provided in Appendix 1.

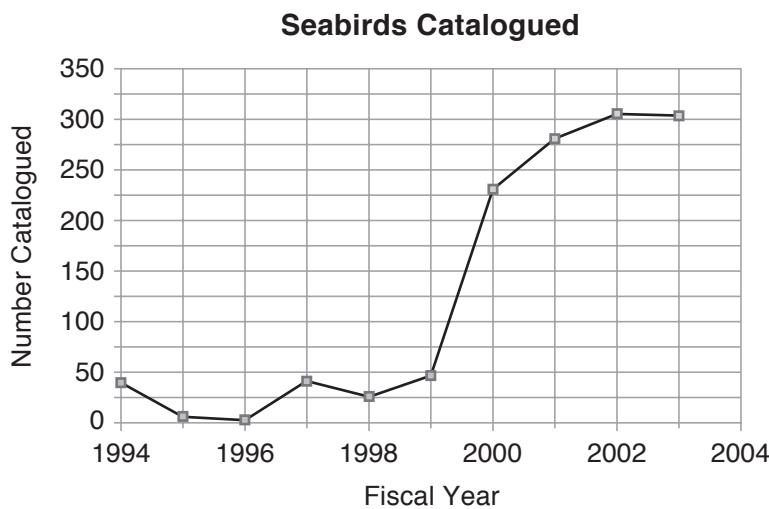

Figure 1. Summary of the number of specimens of 20 seabird genera catalogued into the UAM bird collection annually since 1994. The dramatic increase after 1999 is due to this project, and this rate has continued past the end of the project, as intended.

The seabird specimens preserved and archived represent the core product and result of this project. Appendix 2 provides a breakdown of the taxonomic and geographic distributions of these specimens. Both taxonomic and geographic coverage were broad, as befits the diverse coastal regions and avifauna of the state. We processed both salvaged and actively collected specimens, and we chose birds to process based on sample gaps. Many excellent series were preserved, increasing the scientific utility of the specimens by enhancing the sample sizes available. These specimens will provide an excellent baseline of samples upon which to undertake future studies contrasting changes across time and space.

This project has had a considerable positive effect in raising the profile of seabird specimen archiving and in publicizing its importance. Consequently, more specimens are being salvaged and more are being deposited here. Further, the scientific importance of these activities is causing others to be more proactive in these efforts. One important example of this is the U.S. Fish & Wildlife Service (USFWS)-initiated project “Demography of seabirds in Alaska fisheries,” in which we are processing birds obtained by USFWS and the National Oceanic and Atmospheric Administration (NOAA) as by-catch in the longline fishery. This project supports an undergraduate student. Another important example is the increased deposition of the federally-listed sea ducks *Somateria fischeri* (Spectacled Eider; $N = 8$) and *Polysticta stelleri* (Steller’s Eider; $N = 11$; Appendix 2). The increased attention that these species are receiving as federally-listed taxa increased the rate at which dead individuals have been found and salvaged. Historically, getting these specimens into an appropriate repository has not always been done. We’ve even received specimens after the necropsy process, which is a great positive step in cooperation for long-term sample archiving. These specimens have incalculable scientific value, and we’re pleased that others are beginning to realize this and deposit them with UAM.

Collection Growth

Figure 1, which summarizes 20 genera, shows that this project continues to have a major impact on UAM seabird holdings. It is important to reiterate that these samples, representing unique points in time and geographic space, are not being replicated elsewhere.

During the course of the project our archiving of specimens taken for specific research projects became an important added benefit to this sample archiving project. Vouchering this material is particularly good in two ways. First, it preserves specimens already known to be useful for pertinent scientific questions. Secondly, it maximizes the scientific utility of birds already collected by making them available to other researchers for other questions. This project was important in cementing such research/repository partnerships, and the quality of the preserved material is enhanced by being used for research before it is even deposited. Alan Springer was particularly important in these efforts, and George Divoky’s work also contributed high-quality specimens.

Collection Use

Use of archived seabirds in the UAM collection has increased in frequency and diversity during this project—largely as a consequence of the increased profile that seabirds have had here and the increased recognition of UAM as a seabird sample archive. The rate of seabird sample loans and visits to examine seabird specimens has approximately doubled during the project’s three years (Table 1).

The collection is accessible to users through appointment and specimen loans. Guidelines for prospective users are available through our web site (<http://www.uaf.edu/museum/bird>).

Our database is presently undergoing a major transition; a preview can be seen at (<http://arctos.database.museum/SpecimenSearch.cfm>). The bird collection is of course integrally related to the Alaska Frozen Tissue Collection (<http://www.uaf.edu/museum/af>), a UAM resource with an important history of development with CMI-MMS funding.

Two of our first loans of seabird samples went straight to the purpose behind this project. One was for Vicki Friesen's (Queen's University, Ontario) genetics study comparing Prince William Sound seabird populations with Aleutian populations unaffected by the *Exxon Valdez* oil spill. This request demonstrated the importance of having comparative material available from outside of areas affected (or potentially affected) by petroleum development. Some of these birds were processed specifically to meet this request. Another loan was made to George Divoky (University of Alaska Fairbanks [UAF] Institute of Arctic Biology) for a retrospective study of mercury loads as reflected in feathers (Arctic Ocean).

Table 1. Annual rates of seabird sample loans and on-site visits to examine seabird specimens in the UAM bird collection during this project.

	Loans	Visits
Year 1	3	2
Year 2	3	4
Year 3	4	7

A loan of seabird samples for stable isotope analyses was used in a UAF master's thesis [Abromaitis 2000]. Rocque [2003] also used seabird samples from this project for stable isotope analyses. Kirstin Janssen, a Ph.D. student at the University of Tromsø, Norway, is using genetic samples for her dissertation research on color polymorphisms and population genetics in Parasitic Jaegers (*Stercorarius parasiticus*). Nick Mundy of Cambridge University is using genetic samples of Alaska's other two species of jaeger (*Stercorarius*) for similar studies (and he and Janssen are collaborating with the use of tissues sent earlier to Norway). Laurène Gay, a Ph.D. student at the Centre for Functional and Evolutive Ecology, National Centre for Scientific Research (CEFE CNRS) in Montpellier, France, is using tissues of several gull species in his research on hybridization and selection in large, white-headed gulls. Kevin McCracken and Sarah Sonsthagen are using genetic samples of archived Common Eider (*Somateria mollissima*) tissues for a CMI-MMS-funded study of the genetics of this species in Alaska. Dr. McCracken is also studying genetics in other Holarctic ducks. Peter Houde, New Mexico State University, is using puffin genetic samples in his molecular phylogenetics research. University of Washington Ph.D. student Hollie Walsh is using albatross (*Diomedea*) genetic samples in her genetics research. George Divoky is using

Black Guillemot (*Cephus grylle*) feathers for stable isotope studies. Scott Hatch (U.S. Geological Survey, Biological Resources Division [USGS-BRD]) is examining *Fulmarus glacialis* population genetics. Other research projects are in development; few are yet published, but a list of those that are is given in the Study Products section.

Many visits have been made to the UAM bird collection during the course of the project to examine eider specimens, reflecting the attention being paid to this group of seabirds due to population declines and the federal listing of two eider species. These uses have varied from artists using eider specimens as models (several independent visits) to students working with eider specimens for their research projects, to researchers examining historic material of the two threatened species (several independent visits). It is clear that UAM is now an important repository for this group of birds, and this project made a big difference in the number of specimens available (see Appendix 2). Thus far there has not been competition for use of these specimens; many researchers are benefiting from them.

Other visiting researchers found recent material preserved by this project to be useful in their studies. One was studying Alaska gulls; another was synthesizing data on the birds of the Pribilofs. Jeb and April Benson came to use the *Fratercula cirrhata* (Tufted Puffin) specimens for the Life Histories of North American Birds account, and Chris Thompson came to examine specimens of *Brachyramphus* murrelets for his study of molts and plumages in this group. Robert Day (ABR, Inc.) used the collection to continue his studies of *Aethia pygmaea* (Whiskered Auklet). An archaeologist found our seabird bones to be useful for his research project, and recent seabird specimens also proved useful for a summary of the birds of St. Matthew Island in the Bering Sea [Winker et al. 2002].

Many other loans continue to be made to researchers from around the world studying Alaska seabirds. A scientist from Belgium is using the UAM bird collection to study variation in gull wings (*Larus*), and most of the specimens he is using are the direct result of this project. We sent specimen data for North Pacific *Puffinus griseus* to a researcher in New Zealand (where these birds breed; the North Pacific is part of their nonbreeding range). We also sent data to a researcher in France studying the sex and age effects of longline mortalities in albatross.

Discussion

The activities surrounding this project and the specimens generated from it have had a snowball effect in both the interest and use of seabird specimens at UAM. The influx of seabird material was greater than we had predicted, and our processing of these samples met the challenge, resulting in substantially more preserved specimens than anticipated at the project's beginning. In sum, the project has been a resounding success. This success will be built upon as we continue to preserve and archive seabirds and researchers continue to capitalize on this important and growing research resource.

Acknowledgements

We remain grateful to all biologists who obtain dead seabirds, label and freeze them, and deposit them with the University of Alaska Museum. Particularly important on this project have been the efforts of Robert Suydam, Alan Springer, Jeff Williams, Vernon Byrd, John Piatt, Shannon Fitzgerald, Ed Melvin, Sharon Davis, George Divoky, and Paula Cullenberg. This work is conducted under a series of permits from the U.S. Fish & Wildlife Service, Convention on the International Trade in Endangered Species (CITES), the Alaska Department of Fish and Game, UAF Institutional Animal Care and Use Committee (IACUC), and the U.S. Department of Agriculture Animal and Plant Health Inspection Service (USDA-APHIS). We thank permitting officers for their continued facilitation of permits. Financial support for this project came from the Minerals Management Service through the University of Alaska Coastal Marine Institute, and the University of Alaska Museum.

Study Products

These theses and publications are not direct products of this project, but they have each used specimens resulting from it in their development:

- Abromaitis, G.E. 2000. A retrospective assessment of primary productivity on the Bering and Chukchi sea shelves using stable isotope ratios in seabirds. M.S. thesis, University of Alaska Fairbanks.
- Piatt, J.F., and A.S. Kitaysky. 2002. Horned Puffin (*Fratercula corniculata*), p. 1–27. In A. Poole and F. Gill [eds.], *The Birds of North America*, No. 611. The Birds of North America, Inc., Philadelphia.
- Rocque, D.A. 2003. Intrinsic markers in avian populations: Explorations in stable isotopes, contaminants, and genetics. Ph.D. dissertation, University of Alaska Fairbanks.
- Rocque, D.A., and K. Winker. 2004. Biomonitoring of contaminants in birds from two trophic levels in the North Pacific. *Environ. Toxicol. Chem.* 23(3):759–766.
- Winker, K., D.D. Gibson, A.L. Sowls, B.E. Lawhead, P.D. Martin and E.P. Hoberg. 2002. The birds of St. Matthew Island, Bering Sea. *Wilson Bull.* 114(4):491–509.

In addition there were approximately five presentations on this project.

Environmental Toxicology and Chemistry: Vol. 23, No. 3, p. 759–766.

BIOMONITORING OF CONTAMINANTS AMONG BIRDS FROM TWO TROPHIC LEVELS IN THE NORTH PACIFIC. Deborah A. Rocque and Kevin Winker. *University of Alaska Museum, 907 Yukon Drive, Fairbanks, AK 99775-6960, USA*

Abstract—The presence and accumulation of persistent contaminants at high latitudes from long-range transport is an important environmental issue. Atmospheric transport has been identified as the source of pollutants in several arctic ecosystems and has the potential to severely impact high-latitude populations. Elevated levels of contaminants in Aleutian Island avifauna have been documented, but the great distance from potential industrial sources and the region's complex military history have confounded identification of contaminant origins. We sampled bird species across the natural longitudinal transect of the Aleutian Archipelago to test three contaminant source hypotheses. We detected patterns in some polychlorinated biphenyl congeners and mercury that indicate abandoned military installations as likely local point sources. Carbon isotopes were distinct among island groups, enabling us to rule out transfer through migratory prey species as a contaminant source. The long-range transport hypothesis was supported by significant west-to-east declines in contaminant concentrations for most detected organochlorines and some trace metals. Although relatively low at present, concentrations may increase in Aleutian fauna as Asian industrialization increases and emitted contaminants are atmospherically transported into the region, necessitating continued monitoring in this unique ecosystem.

Key words: Atmospheric transport, Aleutian Islands, Contaminants, Birds, Stable isotopes.

Figure 1. Relationships between atmospherically transported organochlorines in muscle tissue (see Table 1 for sample sizes) of cormorants (*Phalacrocorax* spp.) and relative longitude of sampled Aleutian Islands, Alaska. A) HCB (longitude = -1.24×10^{-8} [HCB] + 0.0328, $R^2 = 0.0709$, $P = 0.0201$); B) p,p'-DDE (longitude = -4.21×10^{-8} [DDE] + 0.0138, $R^2 = 0.0571$, $P = 0.0376$); C) Σ PCB (longitude = -1.62×10^{-7} [Σ PCB] + 0.0472, $R^2 = 0.0618$, $P = 0.0303$); and D) trans-nonachlor (longitude = -1.67×10^{-8} [trans-nonachlor] + 0.0047, $R^2 = 0.0563$, $P = 0.0391$).

Appendix 2

Alphabetical list of seabird specimens of 20 genera processed and archived into the UAM bird collection during the project ($N = 962$). This is a list of all seabirds processed and archived during the project period; although as we processed them we counted specific birds as project-related, this information is not recorded in our collection database.
