Foreword

The National Standard Reference Data System provides access to the quantitative data of physical science, critically evaluated and compiled for convenience and readily accessible through a variety of distribution channels. The System was established in 1963 by action of the President's Office of Science and Technology and the Federal Council for Science and Technology, and responsibility to administer it was assigned to the National Bureau of Standards.

NSRDS receives advice and planning assistance from a Review Committee of the National Research Council of the National Academy of Sciences-National Academy of Engineering. A number of Advisory Panels, each concerned with a single technical area, meet regularly to examine major portions of the program, assign relative priorities, and identify specific key problems in need of further attention. For selected specific topics, the Advisory Panels sponsor subpanels which make detailed studies of users' needs, the present state of knowledge, and existing data resources as a basis for recommending one or more data compilation activities. This assembly of advisory services contributes greatly to the guidance of NSRDS activities.

The System now includes a complex of data centers and other activities in academic institutions and other laboratories. Components of the NSRDS produce compilations of critically evaluated data, reviews of the state of quantitative knowledge in specialized areas, and computations of useful functions derived from standard reference data. The centers and projects also establish criteria for evaluation and compilation of data and recommend improvements in experimental techniques. They are normally associated with research in the relevant field.

The technical scope of NSRDS is indicated by the categories of projects active or being planned: nuclear properties, atomic and molecular properties, solid state properties, thermodynamic and transport properties, chemical kinetics, and colloid and surface properties.

Reliable data on the properties of matter and materials are a major foundation of scientific and technical progress. Such important activities as basic scientific research, industrial quality control, development of new materials for building and other technologies, measuring and correcting environmental pollution depend on quality reference data. In NSRDS, the Bureau's responsibility to support American science, industry, and commerce is vitally fulfilled.

A handwritten signature in black ink, reading "E. Ambler." The signature is fluid and cursive, with a large initial "E" and a period at the end.

ERNEST AMBLER, *Acting Director*

Preface

This report is one of a series of data publications on radiation chemistry; the aim of the series is to compile, evaluate, and present the numerical results on processes occurring in systems which have been subjected to ionizing radiation. Various kinds of data are important in radiation chemistry. The quantities which were measured first were the observed radiation yields or G values (molecules formed or destroyed per 100 eV). Various indirect methods based on G values have been used to determine yields of transient species and relative rates of reactions. The spectral properties (optical, electron spin resonance) of transients have provided a direct method for their identification, and rates of the very fast reactions of transients which occur in irradiated systems have been measured directly by spectroscopic methods. Conductivity and luminescence methods have also provided a means of measuring properties of transients and their kinetics. Some reactions which occur in irradiated systems have also been studied by other methods, such as photochemistry, electric discharge, ultrasonics, chemical initiation, electron impact, etc. The emphasis in these publications is on the data of radiation chemistry, but where other pertinent data exist, they are included.

The data of radiation chemistry are voluminous; thousands of systems have been investigated. As a result there are certain collections, *e.g.* rate constants of particular types of reactions or certain properties of transients, for which tabulations of the data are considered essential, but for which critical assessment of each value is impossible. On the other hand, certain systems and properties have been studied so extensively that critical examination of these data is desirable and timely. Authors of this series of data publications have been asked to evaluate the extent to which the data can be critically assessed, to describe their criteria for evaluation, and to designate preferred values whenever possible.

Selected Specific Rates of Reactions of Transients from Water in Aqueous Solution. III. Hydroxyl Radical and Perohydroxyl Radical and their Radical Ions

Farhataziz and Alberta B. Ross

Radiation Chemistry Data Center, Radiation Laboratory*,
University of Notre Dame,
Notre Dame, IN 46556

Rates of reactions of OH and HO₂ with organic and inorganic molecules, ions and transients in aqueous solution have been tabulated, as well as the rates for the corresponding radical ions in aqueous solution (O⁻ and O₂⁻). Most of the rates have been obtained by radiation chemistry methods, both pulsed and steady-state; data from photochemistry and thermal methods are also included. Rates for over one thousand reactions are listed.

Key words: Aqueous solution; chemical kinetics; data compilation; hydroxyl radical; oxide radical ion; perhydroxyl radical; radiation chemistry; rates; superoxide ion.

1. Introduction

The short-lived products of water radiolysis for low LET radiation (cobalt-60 gamma rays, X-rays, and electrons with energies of about 30 keV and above) are e_{aq}⁻, H and OH. In the presence of oxygen, hydrated electrons and hydrogen atoms are converted to other short-lived species, O₂⁻ and HO₂. The pK_a's of OH and HO₂ are 11.9 (65-0386, 66-0424) and 4.88 (70-0304), respectively; i.e., O⁻ and O₂⁻ can be produced from the equilibria:

Thus, by adjusting only pH and the concentration of O₂ in water, one can produce e_{aq}⁻, H, OH, HO₂, O₂⁻ and O⁻. All of these species have been characterized and their reactions with hundreds of inorganic and organic compounds have been studied. In the previous compilations, NSRDS-NBS 43 and Supplement (73-0030, 75-0002) and NSRDS-NBS 51 (75-0001), the specific rate constants for e_{aq}⁻ and H have been collected. The present compilation is an extension of the series and covers the specific rates for the reactions of OH, HO₂, O⁻, and O₂⁻. The literature is covered up to the latter part of 1975.

Methods

The majority of the data in this compilation are from investigations in radiation chemistry. However, data from photochemistry, Fenton's reaction, and other methods are also included. The rate constants of short-lived species are measured by *steady-state* and *pulse techniques*. The *steady-state* investigations yield ratios of rate constants which are deduced from an assumed mechanism. Values of specific rates

*The Radiation Laboratory is operated under contract with The Energy Research and Development Administration. The work of the Center is supported jointly by The National Bureau of Standards, Office of Standard Reference Data and The Energy Research and Development Administration. This is ERDA Document COO-38-816.

from steady-state investigations may be as accurate as those measured by other methods. However, in many cases, the mechanisms are complex and the values measured with steady-state techniques must be accepted with caution. By *pulse techniques*, it is possible to study a reaction directly if one can either measure disappearance of a reactant (*decay kinetics*, d.k.) or formation of a product (*product buildup kinetics*, p.b.k.) during the course of a reaction by methods such as optical spectroscopy, electrical conductivity, etc. Unfortunately, due to experimental difficulties, such investigations are possible for only a few of the reactions compiled in these tables. The specific rates for other reactions have been measured by *competition kinetics* (c.k.) using pulse techniques.

In the present compilation an attempt was made to be as comprehensive as possible and include measurements of the rates of the same reaction by various methods, as well as measurements by the same method by different authors; values superseded by later measurements by the same authors have been omitted. Certain relative values are omitted if the standard reactions were not well characterized or if the relative values were in wide disagreement with values measured by several other methods. Examples of such data are those which have been obtained using the decolorization of organic dyes by OH or the oxidation of hydroxylaminedisulfonate ion by OH as the standard reactions.

Extended sections on radiation chemical, photochemical and chemical methods of generating OH and O⁻, and on the methods for rate determination, and the mechanisms for the reactions are found in NSRDS-NBS 46 (73-0299). The reader is also referred to that review for an analysis of complications which may occur in various systems.

Arrangement of Tables

In order to provide for internal consistency in the tables, values for rates of a number of competing reactions have been chosen to convert the rate ratios into relative rates. Those values are listed in table 1 and have been taken, whenever possible, from the review of Dorfman and Adams, NSRDS-NBS 46 (73-0299), where a critical analysis of the hydroxyl radical rate data has been made and "most reliable values" selected for a number of reactions; some of the values have been taken from an earlier paper on standardization of OH rate data by Willson, Greenstock, Adams, Wageman and Dorfman (71-0578). Many of the values chosen are the most recent directly determined rates; the references to those determinations are cited in the last column of table 1.

Reactions of OH with other transient species from water are listed in table 2. The reactions of inorganic solutes with OH are listed in table 3 in alphabetical order by main element. The reactions of organic solutes with OH are listed in table 4 in alphabetical order by name. In most cases IUPAC nomenclature has been used. The reactions of O⁻ and HO₂(O₂⁻) are listed by the same arrangement in tables 5 and 6, respectively.

The format of the tables is similar to previous parts of this series. Reactions are included in column 2 when products or mechanism have been studied. When several reactions are given, the reactions are labelled (I), (II), etc. and the rates in columns 4 and 5 are labelled (I), (II), k_I , k_{II} , etc.; if the rate in column 4 or 5 is not so labelled the value represents the sum of the rates for all contributing reactions. Reactions are second order and the rates have the units $\text{dm}^3\text{mol}^{-1}\text{s}^{-1}$ unless otherwise specified in the tables. Values for radical combination and disproportionation rates (entries 3.3, 4.5, 5.4 and 5.35) are for k (and not $2k$ as usually determined) unless it was not clear which was reported, in which case the value is the one given by the authors. Values of k which have been directly measured are given with the error limits as reported by the authors. The ratios of rate constants in the *Ratio* column are given in the form k/k_X where k_X symbolizes the rate of the competing reaction of the same short-lived species with X. In the *Comments* column ratios may be given as k/k_X or k_X/k_Y where k , k_X , and k_Y are rates of the same short-lived species with the reactant in column 2, X, and Y, respectively. For some of the entries only a ratio is given, but in most cases relative rates have been calculated from the ratios and are listed under the k column. The values of k obtained from ratios are designated as relative (rel.) and have been calculated by using the rates in table 1 (or, in a few cases, using a rate given under *Comments*). At the end of each entry for solutes which have been used in competition studies a list of entry numbers is given in which ratios involving that solute are reported.

Columns are included identifying the source of the radical and the method of measurement; other

information is given under *Comments*, such as activation energy, frequency factor, equilibrium constant, deuterium isotope effect (k_H/k_D). Temperature is 20-25°C, or assumed to be at room temperature, unless otherwise specified.

Abbreviations which have been used are tabulated at the end of this section. References are designated by number as assigned by the Radiation Chemistry Data Center; the first two digits of the number specify the year. The references are given at the end of the tables. A formula index for the solutes refers to entry numbers in the various tables and includes references to the tables of e_{aq}^- and H reactions already published.

^aNumber in parentheses indicates the number of the reaction in the following tables.

^bMost recently reported directly determined rate.

^cCited by Dorfman and Adams in NSRDS-NBS 46 (73-0299) as "most reliable values - values of which the accuracy (within the stated experimental uncertainty or lacking such a statement, within $\pm 30\%$) seems least open to question"; more than one such value is cited in NSRDS-NBS 46 for some reactions.

^dMean value of measured rates with $k(\text{OH} + \text{EtOH}) = 1.85 \times 10^9 \text{dm}^3\text{mol}^{-1}\text{s}^{-1}$ as a secondary reference standard: Willson, Greenstock, Adams, Wageman and Dorfman (71-0578).

^eMean value of relative rates normalized for values listed in this table for competing reactions.

^fReference for the most recently reported directly measured rate.

^gRecent directly determined rates are 5.1×10^9 at natural pH (71-0578) and 5.5×10^9 at pH 9 (72-0047).

5.62	superoxide dismutase (E) Dismutation of O ₂ ⁻ (see 5.35) is catalyzed by E.	5.3-9.5	1.8 x 10 ⁹	—	p.r.	opt.	d.k. at 250 nm (O ₂) as well as 650 nm (Cu); enzyme from bovine blood.	72-3066	
		7	(1.4 ± 0.2) x 10 ⁹	—	p.r.	opt.	d.k. at 245 nm (O ₂); enzyme from bovine blood.	72-1007, 72-3078	
		7.5	(1.2 ± 0.2) x 10 ⁹	—	p.r.	opt.	d.k. at 650 nm (E); soln. contains Na formate and EDTA; enzyme from bovine blood.	73-0109	
		5.0-9.5	~ 2 x 10 ⁹ (rel.)	—	chem., biol.	opt.	c.k. (bovine Cu-Zn enzyme); assume	73-3052	
		5.7-10.5	1.5 x 10 ⁹	—	p.r.	opt.	d.k. at 690 nm; Cu enzyme from human blood.	73-3132	
		9.0-9.9	(2.37 ± 0.18) x 10 ⁹	—	p.r.	opt.	d.k. at 250 nm; bovine Cu-Zn enzyme; supersedes 72-3066.	74-3017	
		7.9-9-10.2	(1.3 ± 0.15) x 10 ⁹ 2.3 x 10 ⁹	—	p.r. elec.	opt. pol.	d.k. at 248 nm; <i>E. coli</i> Mn enzyme. obs. increased O ₂ formn. with enzyme addn.	74-3059 74-3132	
5.63	Paraquat radical See 4,4-dimethyl-1,1'-bipyridylum chloride (5.54). 2,3,5,6-tetramethylbenzoquinone See duroquinone (5.55a). tetranitromethane	—	(2.0 ± 0.4) x 10 ⁹	—	p.r.	opt.	p.b.k.	64-0133	
		O ₂ ⁻ + C(NO ₂) ₄ → O ₂	5.6-6.2	(1.9 ± 0.4) x 10 ⁹	—	p.r.	opt.	p.b.k.	65-0183
		+ C(NO ₂) ₃ + NO ₂	6.2						
5.64	tiron (1,2-dihydroxybenzene-3,5-disulfonate ion)	7	5 x 10 ⁸	—	p.r.	opt.	p.b.k. at 400 nm.	75-1087	
		7	1.5 x 10 ⁸ (rel.)	k/k _{benzoquinone} = 0.17	p.r.	opt.	c.k.; assume k _{benzoquinone} = 9 x 10 ⁸ .	75-1087	
5.65	Vitamin K ₁	7	< 2 x 10 ⁵	—	p.r.	opt.	detd. from equil. const. and d.k. of semiquinone.	73-0125	

Formula index

The following formula list refers to entry numbers, not only in the preceding tables, but also in the tables of rates of hydrated electron and hydrogen atom reactions published as part I (and Supplemental data) and part II. The first digit of the entry number identifies the section of the tables where the entry can be found.

1. Part I. Hydrated electron 73-0030 (NSRDS-NBS 43)
- S1. Hydrated electron, Supplemental data 75-0002 (NSRDS-NBS 43-Supp)
2. Part II. Hydrogen Atom 75-0001 (NSRDS-NBS 51)
3. Part III. Hydroxyl radical (this work, tables 2-4)
4. Part III. Oxide ion (this work, table 5)
5. Part III. Perhydroxyl radical and superoxide ion (this work, table 6).

Thus, there are entries for Ag^+ in the tables of hydrated electron reactions (1.11), hydrogen atom reactions (2.5) and hydroxyl radical reactions (3.8), while BrO_4^- entries are found in the supplemental tables for hydrated electrons (S1.6), hydroxyl radical reactions (3.17), and oxide ion reactions (4.11).
