1109 Transmission of Measles Among a Highly Vaccinated School Population - Anchorage, Alaska, 1998

1112 Preemptive State Tobacco-Control Laws - United States, 1982-1998
1115 Decrease in AIDS-Related Mortality in a State Correctional System New York, 1995-1998
1117 Update: Multistate Outbreak of Listeriosis - United States, 1998-1999

## Transmission of Measles Among a Highly Vaccinated School Population Anchorage, Alaska, 1998

During August 10-November 23, 1998, 33 confirmed* measles cases were reported to the Anchorage Department of Health and Human Services and the Alaska Department of Health and Social Services (ADHSS). Of these, 26 cases were confirmed by positive rubeola $\lg \mathrm{M}$ antibody test, and seven met the clinical case definition. This was the largest outbreak of measles in the United States since 1996 (1,2). This report summarizes results of the epidemiologic investigation conducted by ADHSS and underscores the importance of second-dose requirements for measles vaccine.

On August 10, a 4 -year-old child (index case) visiting from Japan had rash onset of measles while in Anchorage (Figure 1). The child was hospitalized for 1 day, and measles was diagnosed by positive rubeola $\operatorname{lgM}$ enzyme-linked immunosorbent assay. No measles virus cultures were obtained. No cases were reported during the following 3 weeks, when secondary cases would have been expected. On September 5, 26 days after onset of the imported case, a 16 -year-old high school student developed measles, confirmed by lgM testing. Subsequently, 15 other students and one teacher at the same high school developed measles during September 14-October 4; 12 cases were laboratory confirmed. In addition, four laboratory-confirmed cases and two clinical cases occurred at six other Anchorage schools; one case-patient attended two schools while infectious (from 7 days before to 4 days after rash onset). Eight other confirmed cases occurred among young adults not associated with schools, and one case occurred in a 2 -year-old child.

The 33 case-patients ranged in age from 2 to 28 years (median: 16 years). Twentynine case-patients had received at least one dose of measles-containing vaccine (MCV) at or after age 12 months; one person with laboratory-confirmed measles had received two appropriately spaced doses of measles-mumps-rubella vaccine (MMR). No serious complications or deaths were reported.

At the high school where the 17 cases occurred, based on school records, only one of 2186 students had not received at least one dose of MCV before the outbreak;

## U.S. DEPARTMENT OF HEALTH AND HUMAN SERVICES

FIGURE 1. Number of confirmed* measles cases, by date of rash onset, by 3-day interval — Anchorage, Alaska, August 10-November 23, 1998 ${ }^{\dagger}$

*A confirmed case was laboratory confirmed or met the clinical case definition and was epidemiologically linked to a confirmed case. A clinical case was defined as an illness characterized by generalized rash lasting $\geq 3$ days; temperature $\geq 101 \mathrm{~F}(\geq 38.3 \mathrm{C}$ ); and either cough, coryza, or conjunctivitis; $\mathrm{n}=33$.
${ }^{\dagger} \mathrm{n}=33$.
${ }^{\S}$ Measles-containing vaccine.
1057 (49\%) had received one dose of MCV, and 1112 (51\%) had received two or more doses. Estimated vaccine efficacy for two or more doses of MCV was $100 \%$.

Sequence analysis was conducted on the region coding for the COOH terminus of the nucleoprotein for measles virus cultured from three outbreak cases. All three isolates had identical sequences and were classified as genotype D5 (3). This strain was almost identical to wild measles virus strains circulating in Japan in 1998 and was not related to the strain isolated from an outbreak in Juneau in 1996, the most recent isolate available from Alaska (4).

Before 1996, all students attending public and private schools in Alaska were required to have documentation of a single dose of MCV (or a valid medical or religious exemption). Beginning in September 1996, all students entering kindergarten or first grade were required to have two doses of MCV. As a result, school records indicate that virtually all students in kindergarten through third grade as of fall 1998 had received two doses of MMR. However, the proportion of students in grades 4-12 that had two doses was unknown.

In response to the outbreak, ADHSS issued an emergency order requiring that all Anchorage schoolchildren have two doses of MCV by November 16, 1998 (Figure 1). Subsequently, the order was expanded to require all students in the state to have two doses of MCV by January 4, 1999. Students were vaccinated by their health-care

## Measles - Continued

providers and at special clinics conducted in Anchorage schools. By November 17, 98.6\% of 49,346 Anchorage School District students had provided documentation of two doses of MCV to their schools.
Reported by: B Chandler, MD, Dept of Health and Human Svcs, Municipality of Anchorage; Alaska State Virology Laboratory, Fairbanks; L Wood, MPA, E Funk, MD, M Beller, MD, J Middaugh, MD, State Epidemiologist, Alaska Dept of Health and Social Svcs. Measles Virus Section, Respiratory and Enteric Diseases Br, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases; Measles Elimination Activity, Child Vaccine Preventable Diseases Br, Epidemiology and Surveillance Div, National Immunization Program; Div of Applied Public Health Training, Epidemiology Program Office; and an EIS Officer, CDC.
Editorial Note: The occurrence of this outbreak primarily in one school, despite the extremely high one-dose measles vaccine coverage, demonstrates the importance of school requirements for a second dose of MCV. MCV is highly effective; $<5 \%$ of children who receive one dose fail to develop immunity. However, most children respond to a second dose, and $>99 \%$ of persons aged $\geq 12$ months receiving two or more doses at least 28 days apart develop immunity.

The Advisory Committee on Immunization Practices and the American Academy of Pediatrics recommend that all students from grades kindergarten through 12 have two doses of MCV by 2001 (5,6). As of the 1998-99 school year, state school requirements for two-dose measles vaccination have covered approximately $53 \%$ of U.S. schoolchildren (CDC, unpublished data, 1998). The vigorous response by public health and school officials in Anchorage to this outbreak in accelerating second-dose measles vaccination among schoolchildren may have limited the extent of this outbreak and will help prevent future outbreaks in Alaska schools.

Monitoring of viral genotypes is an important component of measles surveillance. Genotyping provided evidence that the Anchorage outbreak was due to importation from Japan; however, no specimens were obtained from the index case. This underscores the importance of obtaining throat and urine specimens from suspected measles cases immediately after rash onset. Although no endemic measles virus is circulating in the United States, outbreaks may continue to occur when imported measles virus is introduced into a high-risk setting (e.g., schools with incomplete seconddose MCV coverage).

## Preemptive State Tobacco-Control Laws — United States, 1982-1998

Cigarette smoking is the leading preventable cause of death in the United States (1). Environmental and policy interventions, particularly tobacco-control laws and regulations, are an important means to prevent and reduce tobacco use (2). For this study, preemptive legislation was defined as legislation that prevents any local jurisdiction from enacting restrictions that are more stringent than the state law or restrictions that may vary from the state law. One of the national health objectives for 2000 is to reduce to zero the number of states with preemptive smokefree indoor air laws (objective 3.25) (3); a proposed objective for 2010 is to reduce the number of states with any preemptive tobacco-control laws to zero. To document trends in preemptive tobacco-control legislation at the state level, CDC identified state preemptive provisions and their effective dates from June 1982 (the oldest provision currently in effect) to September 1998. This report summarizes the results of this analysis, which indicate an increase in the number of preemptive provisions from 1982 to 1996; no preemptive provisions in tobacco-control laws have been enacted since 1996.

CDC gathered data about state tobacco-control laws from an online legal research database to monitor such laws in four primary areas: smokefree indoor air, minors' access, marketing, and excise taxes. Data included the preemptive provisions of these laws. For this study, preemptive provisions are presented in three categories: smokefree indoor air (applying to restrictions on government or private worksites or restaurants), minors' access (addressing restrictions on sales to youth, vending machines, or distribution), and marketing (including restrictions on tobacco product sampling, display, promotion, or labeling). A multistep process was used to identify the month and year the preemptive provisions of these laws took effect. The process included identifying the history of the law by finding the records of each state's legislative session in a given year and analyzing the session laws to determine the effective date of the law's provision.

From 1982 through September 1998, 31 states incorporated preemptive provisions in their tobacco-control laws. Maine was the only state to repeal its preemptive provision (on tobacco displays, product placement, and time of sale) during the study period. Some preemptive provisions are very narrow. For example, in New York, the state government has precedence over local government restrictions on the free distribution of samples of tobacco products. Other provisions are broad. For example, in Tennessee, minors' access laws preempt local legislation of all tobacco-control areas.

The number of preemptive provisions included in state tobacco-control laws increased from 1982 through 1996 but has leveled off since 1996 (Figure 1). The results of a linear regression analyzing the number of preemptive provisions per law and the years they became effective indicated a significant increase in the number of provisions from 1993 through 1996. During the 1980s, nine states passed 11 preemptive laws covering 21 provisions. From 1993 to June 1996, 20 states passed 24 preemptive laws covering 82 different provisions. Since July 1996, no preemptive tobacco-control laws have been enacted.

Eighteen states preempt at least one provision of smokefree indoor air restrictions (e.g., government worksites, private worksites, and restaurants); since 1985, 13 states have preempted smokefree indoor air laws in all three areas. Except in South Carolina, all preemptive laws that became effective since 1990 have covered all three areas.

Tobacco-Control Laws - Continued
FIGURE 1. Cumulative number of preemptive provisions in state tobacco-control laws, by year law became effective - United States, 1982-1998

Twenty-one states preempt at least one provision of minors' access restrictions (e.g., sales to youths, vending machines, and distribution). Ten states preempt all three components of minors' access laws. Of 21 states with provisions preempting local minors' access laws, 76\% became effective during July 1993-July 1996.

Seventeen states preempt localities from promulgating their own laws restricting the marketing of tobacco products. Three states (Illinois, Michigan, and West Virginia) specifically preempt restrictions on smokeless tobacco warning labels on billboards; all three of these preemptive provisions became effective during July 1987-September 1988. Fourteen states preempt laws on tobacco display, promotion, or sampling; in $93 \%$ of these states, the preemptions became effective during January 1993-July 1996.

Reported by: Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.
Editorial Note: The findings in this report indicate that most states have preemptive tobacco-control laws. Of the 30 states with such laws, 18 have preemptive provisions for smokefree indoor air. As a result, achievement of the 2000 objective is unlikely.

Tobacco-control policy occurs at the federal, state, and local level. Laws enacted by higher-level jurisdictions benefit the public health by implementing widespread standards. Unless they contain preemptive provisions, legislation at higher levels set minimum requirements and allow the continued passage and enforcement of local ordinances that may establish a greater level of protection of public health (4-6). However, legislation that preempts lower-level action removes control from localities by preventing them from enacting more stringent laws or tailoring laws to address community-specific issues ( $4,6,7$ ). In addition, preemptive laws deter debate over lo-

## Tobacco-Control Laws - Continued

cal ordinances; such debate can educate the community about tobacco, potentially altering social norms about tobacco use (8). Preemptive state laws also can be a barrier to local enforcement because communities not involved in the decision-making process may be less compliant (9).

A 1991 Smokeless Tobacco Council memorandum outlines a strategy to oppose local ordinances and advance statewide antitobacco bills that contain preemption clauses (4). In addition, a Tobacco Institute priority for 1993 was to "encourage and support statewide legislation preempting local laws, including smoking, advertising, sales, and vending restrictions" (10). A potential reason for this strategy is the passage of strong tobacco-control laws at the local level and the logistical difficulties of the tobacco industry to devote resources toward multiple local jurisdictions (4,7).

One limitation of this report is that legislative language is subject to interpretation. Although a law may have been considered preemptive by the definition used in this study, it may not have been implemented as preemptive in a particular state.

Nevertheless, during 1993-1996, the number of tobacco-control laws with preemptive provisions increased significantly. The 1992 federal Synar Amendment, which required states to enact and enforce minors' access laws, resulted in the passage of new laws (many of which included preemptive provisions) in several states. This, coupled with the Tobacco Institute's 1993 stated priority to promote tobacco-control laws with preemptive provisions, may have contributed to this increase. However, since 1996, no preemptive tobacco-control laws have been passed, possibly because of an increased community awareness of the potential harmful effects of preemption and a shift in industry priorities from state to federal restrictions and ongoing litigation.

The importance of laws and policies as a component of comprehensive tobaccocontrol interventions has resulted in their inclusion in surveillance efforts. CDC will continue to monitor progress toward achieving national health objectives for 2000 to reduce tobacco-related morbidity and mortality.

## Decrease in AIDS-Related Mortality in a State Correctional System New York, 1995-1998

The New York State Department of Correctional Services (NYSDOCS) administers one of the largest prison systems in the United States, with a population of approximately 70,000 inmates; in 1995, blinded seroprevalence studies indicated that an estimated 9500 inmates were infected with human immunodeficiency virus (HIV) (1). This report summarizes an analysis of death records of inmates, which indicate a substantial reduction in the acquired immunodeficiency syndrome (AIDS)-related deaths from 1995 through 1998 and describes the programs that may have contributed to this decline.

Cause of death was determined by comparison of death and autopsy reports by an analyst in New York and was confirmed by a second analyst. The first AIDS-related deaths occurred in the NYSDOCS prison system in 1981 (Table 1). Although the number of AIDS-related deaths continued to increase until 1995, most of the increase after 1985 reflected increases in the size of the prison population; the AIDS-related death rate was relatively stable. During the early 1990s, approximately two thirds of deaths occurring among inmates were AIDS-related. From 1990 through 1995, AIDS-related death rates averaged 36.4 per 10,000 inmates (range: 32.5-40.7). This rate declined to 26.3 per 10,000 inmates in 1996 and 8.6 per 10,000 inmates in 1997 (the first year since

[^1]
## AIDS-Related Mortality - Continued

1988 that AIDS was not the major cause of deaths in the NYSDOCS system). Based on data from January-November 1998, the projected annualized AIDS-related death rate for 1998 decreased to 6.1 per 10,000 inmates.

During 1993-June 1998, the annual death rate in the NYSDOCS system from causes other than AIDS has remained stable at an average of 22.4 per 10,000 inmates (range: 20.3-24.2). The number of inmates who met the statutory medical requirements (terminal illness and significant disability) for a medical parole related to HIV/AIDS has declined from 55 in 1995 to 32 in 1996, 13 in 1997, and seven in 1998.
Reported by: LN Wright, MD, New York State Dept of Correctional Svcs; PF Smith, MD, New York State Dept of Health. Div of HIV/AIDS Prevention-Surveillance and Epidemiology, National Center for HIV, STD, and TB Prevention, CDC.
Editorial Note: As of December 31, 1995, 24,226 HIV-infected persons were incarcerated in state and federal prisons, corresponding to $2.3 \%$ of the state and federal prison population in the United States (1); 21\% of these persons had a confirmed AIDS diagnosis. During 1991-1995, AIDS caused approximately one third of all deaths in U.S. prisons (1).

The decline in the AIDS-related deaths observed in the NYSDOCS is similar to that reported for the entire United States during the same time period (2) and corresponds to advancements in treatment of HIV infection (3-7). The finding that death rates for causes other than AIDS were stable suggests that increases in deaths from other causes in HIV-infected persons is not responsible for the decline in AIDS-related mortality. The decrease in the number of inmates granted medical parole related to HIV/AIDS suggests that severe HIV-related morbidity also has declined.

In 1983, the NYSDOCS opened the first in-house medical unit for treatment of prisoners with AIDS at Sing Sing Correctional Facility. The decrease in death rates observed since 1995 followed system-wide efforts in the 70 state prisons to standardize HIV care and to assure that antiretroviral medications and chemoprophylaxis of opportunistic infections are available throughout the system. These efforts included 1) in 1996, establishment of an HIV Treatment Guidelines work group in collaboration with the New York State Department of Health AIDS Institute to develop HIV treatment guidelines and regularly update them to be consistent with nationally recognized best practices; 2) in 1996, initiation of a quarterly live satellite videoconference series in collaboration with Albany Medical Center's Division of HIV Medicine and the New York State STD/HIV Prevention and Training Centers on "Management of HIV/AIDS in the Correctional Setting"; 3) in 1996, development of medical record flow sheets to monitor care being given to HIV-infected prisoners; and 4) in 1997, identification through the NYSDOCS pharmacy system of cases of apparently inappropriate care (e.g., monotherapy with protease inhibitors) and notification of other health-care team members for appropriate review and action.

Proper adherence to antiretroviral medications is essential to avoid development of resistant strains of HIV, but adherence to multidose treatment schedules with exacting requirements for dose-associated fasting or food may be more difficult in prison. Close supervision and intensive patient education is required to assure that prisoner patients understand how to take the medications correctly. Self-administration of medications and directly observed therapy can help resolve some of these issues.

Confidentiality may be more difficult to maintain in a corrections system than it is in other health facilities and may lead some inmates to refuse HIV testing, thus delay-

AIDS-Related Mortality — Continued
ing effective HIV treatment. Another challenge is the frequent transfer of inmates from one prison to another, resulting in frequent changes of primary and specialty providers. Standardization and coordination of treatment across prisons is necessary to ensure optimal care.

One important limitation of the findings of this report is that the precise reason for the decline in AIDS-related deaths in NYSDOCS cannot be determined. The effect attributable to the systematic changes in education and management within the prison system cannot be differentiated from the advances in treatment. Nevertheless, the decline in death rates is associated with the timing of both of these events.

The findings of this report indicate that substantial decreases in AIDS-related deaths are possible in prisons that implement systems to provide up-to-date treatment of HIV infection. Health-care provider training, treatment protocols, and patient education programs that are consistent throughout the prison system can be provided to address the challenges of caring for HIV-infected patients in prisons.

## Update: Multistate Outbreak of Listeriosis — United States, 1998-1999

From early August 1998 through January 6, 1999, at least 50 illnesses caused by a rare strain of the bacterium Listeria monocytogenes, serotype 4 b , have been reported to CDC by 11 states. Six adults have died and two pregnant women have had spontaneous abortions. Reported illness onset dates were during August 2-December 13, 1998. CDC and state and local health departments have identified the vehicle for transmission as hot dogs and possibly deli meats produced under many brand names by one manufacturer. This report updates the investigation of this outbreak (1).

On December 22, the manufacturer, Bil Mar Foods, voluntarily recalled specific production lots of hot dogs and deli meats that might be contaminated. CDC later isolated the outbreak strain of L. monocytogenes from an opened and a previously unopened package of hot dogs manufactured at the company's plant in Zeeland, Michigan. In addition, a different strain of $L$. monocytogenes was isolated from unopened packages of deli meats produced at the same plant.

Listeriosis - Continued
Recalled products bear the establishment numbers EST P261 or EST 6911. The establishment number appears on the outer edge of all packages. The affected products included hot dogs and deli meats with the brand names Ball Park, Bil Mar, Bryan Bunsize, Bryan 3-lb Club Pack, Grillmaster, Hygrade, Mr. Turkey, Sara Lee Deli Meat, and Sara Lee Home Roast brands. Institutions may have received recalled product under other brand names. Packages for the above brand names that carry other establishment numbers are not affected by the recall. Other Sara Lee products that are not meat also are not affected.
Reported by: Ohio Dept of Health. New York State Dept of Health; Food Safety Laboratory, Cornell Univ, New York City Dept of Health. Tennessee Dept of Health. Massachusetts Dept of Public Health. West Virginia Dept of Health and Human Resources. Michigan Dept of Community Health. Connecticut Dept of Public Health. Health Div, Oregon Dept of Human Resources. Vermont Dept of Health. Div of Public Health, Georgia Dept of Human Resources. Minnesota Dept of Community Health. Foodborne and Diarrheal Diseases Br, Div of Bacterial and Mycotic Diseases, National Center for Infectious Diseases; and EIS officers, CDC.
Editorial Note: Healthy persons rarely develop severe illness from Listeria. The illness primarily occurs in pregnant women, newborns, and persons with impaired immunity caused by serious illness, such as acquired immunodeficiency syndrome or cancer. Listeria infections during pregnancy may cause an influenza-like illness with fever and chills, and may lead to loss of the fetus. In other persons, early symptoms can include fever, severe headache, and stiff neck. Illness can begin 2-8 weeks after eating the contaminated food.

Consumers who have the affected product should not eat it, but rather should discard it or return it to the point of purchase. The risk for developing Listeria infection after eating a contaminated product is low. Persons who have eaten a contaminated product and do not have any symptoms do not need any special medical evaluation or treatment, even if they are in high-risk groups. However, persons in high-risk groups who have eaten the contaminated product, and within 2 months become ill with fever or influenza-like illness, should inform their physicians about this exposure. Because of this long incubation period, cases may continue to occur and be reported for several weeks after an effective recall.

Consumers who have questions about the recall or the products involved should contact Bil Mar Foods, telephone (800) 247-8339. Persons who have questions about Listeria should call their physicians or their local or state health departments or visit CDC's World-Wide Web site, http://www.cdc.gov/ncidod/diseases/foodborn/lister.htm. General questions about meat handling should be directed to the U.S. Department of Agriculture's Meat and Poultry Hotline, telephone (800) 535-4555, Monday through Friday from 10 a.m. to 4 p.m. eastern time.

*Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
${ }^{\dagger}$ Preumonia and influenza.
${ }^{\S}$ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
TTotal includes unknown ages.

FIGURE I. Selected notifiable disease reports, comparison of provisional 4-week totals ending January 2, 1999, with historical data - United States

*Ratio of current 4-week total to mean of 154 -week totals (from previous, comparable, and subsequent 4 -week periods for the past 5 years). The point where the hatched area begins is based on the mean and two standard deviations of these 4-week totals.

TABLE I. Summary - provisional cases of selected notifiable diseases, United States, cumulative, week ending January 2, 1999 (52nd Week)

|  | Cum. 1998 |  | Cum. 1998 |
| :---: | :---: | :---: | :---: |
| Anthrax | - | Plague | 8 |
| Brucellosis | 62 | Poliomyelitis, paralytic | 1 |
| Cholera | 12 | Psittacosis | 49 |
| Congenital rubella syndrome | 6 | Rabies, human | - |
| Cryptosporidiosis* | 3,111 | Rocky Mountain spotted fever (RMSF) | 345 |
| Diphtheria | 1 | Streptococcal disease, invasive Group A | 2,067 |
| Encephalitis: California* | 91 | Streptococcal toxic-shock syndrome* | 49 |
| eastern equine* | 4 | Syphilis, congenital ${ }^{\text {f }}$ | 401 |
| St. Louis* | 26 | Tetanus | 34 |
| western equine* | - | Toxic-shock syndrome | 132 |
| Hansen Disease | 105 | Trichinosis | 24 |
| Hantavirus pulmonary syndrome* $\dagger$ | 19 | Typhoid fever | 327 |
| Hemolytic uremic syndrome, post-diarrheal* HIV infection, pediatric*s | 82 262 | Yellow fever | - |

## :no reported cases

Not notifiable in all states.
$\dagger$ Updated weekly from reports to the Division of Viral and Rickettsial Diseases, National Center for Infectious Diseases (NCID),
§ Updated monthly from reports to the Division of HIV/AIDS Prevention-Surveillance and Epidemiology, National Center for
HIV, STD, and TB Prevention (NCHSTP), last update December 27, 1998.
$\llbracket$ Updated from reports to the Division of STD Prevention, NCHSTP.

${ }^{*}$ Mortality data in this table are voluntarily reported from 122 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
${ }^{\dagger}$ Preumonia and influenza.
${ }^{\S}$ Because of changes in reporting methods in this Pennsylvania city, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
TTotal includes unknown ages.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to listserv@listserv.cdc.gov. The body content should read SUBscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/ or from CDC's file transfer protocol server at ftp.cdc.gov. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the MMWR Series, including material to be considered for publication, to: Editor, MMWR Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (888) 232-3228.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

[^0]:    *A confirmed case was laboratory confirmed or met the clinical case definition and was epidemiologically linked to a confirmed case. A clinical case was defined as an illness characterized by generalized rash lasting $\geq 3$ days; temperature $\geq 101 \mathrm{~F}$ ( $\geq 38.3 \mathrm{C}$ ); and either cough, coryza, or conjunctivitis.

[^1]:    * Average daily population for the interval.
    ${ }^{\dagger}$ AIDS cases are calculated on a specified day each month and are averaged for the interval. Period prevalence is reported per 10,000 inmates and is calculated as ([the number of AIDS cases during the interval divided by the prison population] multiplied by 10,000 ). Information on the number of AIDS cases was not collected before 1990.
    ${ }^{5}$ Per 10,000 inmates.
    IThrough November 1998. The number of AIDS-related deaths is the actual number of deaths through November. The AIDS-related death rate is annualized.
