## Hypothermia-Related Deaths — Vermont, October 1994-February 1996

Hypothermia is a lowering of the core body temperature to $\leq 95 \mathrm{~F}$ ( $\leq 35 \mathrm{C}$ ) (1). From 1979 through 1992, a total of 10,550 persons in the United States died from hypothermia, an average of 754 deaths per year (range: 557-1021 deaths) (2). From October 1994 through February 1996, a total of 10 hypothermia-related deaths were reported by the chief medical examiner in Vermont. The average age of the 10 decedents was 62 years (range: 18-88 years); eight were men. Seven decedents were reported to have had histories of mental illness, and alcohol abuse was mentioned on the police or pathology report for two decedents. This report summarizes the investigation of three of these deaths and describes risk factors commonly associated with hypothermia.

Case 1. In March 1995, an 18-year-old woman was found dead, lightly clothed, and covered in snow in the woods behind her house. During the preceding 24 hours, the minimum temperature had been $34 \mathrm{~F}(1 \mathrm{C})$, and 0.04 inches of precipitation had fallen. The woman had a prolonged history of drug abuse. At autopsy, a blood test revealed the presence of benzodiazepines (diazepam, nordiazepam, temazepam, and oxazepam) and diphenhydramine. Drug overdose was listed as the primary cause of death with hypothermia as a contributing cause.

Case 2. In November 1995, a 74-year-old man was found without a coat lying in a field 250 feet from his residence; he was unresponsive and had no palpable pulse. The outside temperature had been $11 \mathrm{~F}(-12 \mathrm{C})$ the previous night. He lived alone and, during the previous 2 weeks, had been reported to be increasingly confused with incidences of wandering and entering wrong apartments. He was last seen at 6:30 p.m. the evening before he was discovered. On admission to the hospital, his core body temperature was $68 \mathrm{~F}(20 \mathrm{C})$, and he died despite resuscitative efforts. He had a medical history of dementia, atheroscelerotic cardiovascular disease, and diabetes. Cold exposure was listed as the primary cause of death, dementia as a secondary cause, and atherosclerotic cardiovascular disease and diabetes as contributory medical conditions.

Case 3. In January 1996, a 46-year-old woman was found frozen in a snow bank; a bottle of liquor was nearby. She had a history of depressive disorder and alcohol abuse. Two days before she was found, she reportedly had been drinking heavily

## Hypothermia-Related Deaths - Continued

when she left one house to walk to another. At autopsy, her blood alcohol concentration (BAC) was $0.33 \mathrm{~g} / \mathrm{dL}$. Hypothermia was listed as the primary cause of death, with ethanol intoxication as a contributing factor.
Reported by: L Siciliano, PL Morrow, MD, Office of the Chief Medical Examiner; J Carney, MD, Vermont Dept of Health. Div of Environmental Hazards and Health Effects, National Center for Environmental Health, CDC.
Editorial Note: From 1979 through 1992, approximately half of all hypothermia deaths in the United States occurred among persons aged $\geq 65$ years (Figure 1). The annual death rate for hypothermia in this age group was 1.3 per 100,000 persons compared with the annual, age-adjusted death rate for hypothermia of 0.3 per 100,000 (3). Elderly persons particularly are at risk for hypothermia because of medical and socioeconomic factors such as underlying diseases, social isolation, and physiologic changes (e.g., lack of appropriate vasoconstriction in response to cold environments, decreased basal metabolic rate, and impaired shivering mechanism). The risk for hypothermia-related death also was greater in men than in women (age-adjusted death rates, 2.0 versus 0.7 per 100,000 among persons aged $\geq 65$ years, respectively); reasons for this difference have not been defined.

Ethanol abuse, which is strongly associated with hypothermia, results in vasodilation and interferes with peripheral vasoconstriction, an important physiologic mechanism of defense against the cold. Neuroleptic drugs also predispose a person to hypothermia by inducing vasodilation and suppressing the shivering response. The hypothermic effects of these types of drugs are amplified by lower ambient tempera-

FIGURE 1. Annual death rate* associated with hypothermia ${ }^{\dagger}$, by age group and sex - United States, 1979-1992

[^0]
## Hypothermia-Related Deaths - Continued

tures. Other risk factors for hypothermia include hypothyroidism, mental illness, dehydration and starvation, homelessness and poverty, immobilizing illness, and sustained contact with materials that promote conductive heat loss (e.g., water, solvents, and metals) (1).

Hypothermia-related morbidity and mortality can be prevented by early recognition and prompt medical care. Early indications of hypothermia include shivering, numbness, fatigue, poor coordination, slurred speech, impaired mentation, blueness or puffiness of the skin, and irrationality. The use of insulated clothing that does not retain moisture and appropriate head gear can assist in preventing cold-related illness because $30 \%$ of heat loss comes from the head. Immersion in water and wet clothing during cold weather should be avoided. In addition, persons who are outdoors in cold conditions should increase fluid and calorie intake, abstain from consuming alcoholic beverages, and avoid overexertion and sweating.

## Estimates of Retailers Willing to Sell Tobacco to Minors California, August-September 1995 and June-July 1996

The prevalence of tobacco use among adolescents is increasing, and the most common source of tobacco products for persons aged <18 years (minors) is retail stores ( 1 ). In 1991, an estimated 29.6 million packs of cigarettes were sold illegally to minors in California, and an estimated 255 million packs were sold illegally to minors nationwide (2). Federal Iaw (i.e., the Synar Amendment*) enacted in July 1992 requires all states that receive federal funds for prevention and treatment of substance abuse to have and enforce laws prohibiting the sale or distribution of tobacco to minors, conduct annual statewide inspections of over-the-counter tobacco outlets and vending machines to assess the statewide rate of illegal tobacco sales to minors, and develop a plan to decrease the illegal sales rate to $\leq 20 \%$ over several years (3). On September 28, 1994, California enacted the Stop Tobacco Access to Kids Enforcement (STAKE) Act ${ }^{\dagger}$, which requires that 1) tobacco retailers (i.e., vendors) post warning signs at each point of purchase and check the identification of persons who appear aged <18 years; 2) the California Department of Health Services (CDHS) develop a statewide enforcement program and establish a toll-free telephone number for reporting observed illegal tobacco sales to minors; and 3) CDHS annually assess and report the rate of illegal sales of tobacco products to minors. This report describes the retailer education and enforcement program and summarizes the results of the first two annual assessments (Youth Tobacco Purchase Surveys [YTPSs]). The findings indicate

[^1]
## Tobacco Sales to Minors - Continued

that, from August-September 1995 to June-July 1996, among over-the-counter tobacco outlets the percentage of retailers who asked for age identification increased substantially, the percentage of stores displaying warning signs on age restrictions increased, and the percentage of retailers willing to sell tobacco products to minors decreased.

## Education About and Enforcement of Youth Access Laws

In response to provisions of the STAKE Act, in August 1995 CDHS initiated an ongoing public and retailer education program before the enforcement of the law began on December 27, 1995. The education program consisted of an advertisement in a retail trade journal; a statewide press conference; paid radio and television commercials and billboard advertisements promoting a toll-free telephone number; a direct mailing of educational materials and warning signs to approximately 27,000 retailers; and educational materials provided to local government officials, retail trade groups, local health groups, chambers of commerce, and state legislators. In addition, 120 local and regional community organizations conducted educational, policy development, and media activities to stimulate compliance with youth access laws.

The STAKE Act requires that the CDHS statewide enforcement program include 15and 16 -year-old minors for unannounced inspections of tobacco retailers. Civil penalties of $\$ 200-\$ 6000$ can be levied against the business owner depending on the number of offenses during a 5-year period. During December 27, 1995-June 10, 1996 (the period before the second YTPS began), CDHS conducted 865 unannounced inspections in 22 of the state's 58 counties. As of December 16, 1996, fines totaling \$65,550 had been paid by 258 business owners among the 286 who were in violation of the STAKE Act during December 27, 1995-June 10, 1996, and 28 business owners are involved in litigation or further administrative processing with CDHS.

## Youth Tobacco Purchase Surveys

The 1995 YTPS was the first state-representative random survey in California of illegal tobacco sales to minors and was conducted during August 2-September 7, 1995. A second YTPS was conducted during June 11-July 26, 1996, after initiation of the retailer education campaign and enforcement program. The YTPS methodology was designed to permit statistically valid statewide estimates and year-to-year comparisons of over-the-counter tobacco sales to minors. The California State Board of Equalization provided a list of businesses most likely to sell tobacco over the counter, including all convenience stores, gas stations, drug stores, liquor stores, supermarkets, and cigar stores in California. Using simple random sampling, sample sizes of 405 for 1995 and 434 for 1996 were obtained after eliminating stores that were no longer in business, were not tobacco outlets, could not be located (four in 1995 and 21 in 1996), or were considered unsafe by the survey teams (none in 1995 and nine in 1996). Odds ratios and $p$ values were calculated for the change from 1995 to 1996. The odds ratios for asking age and/or for identification, presence of warning signs, and total sales were adjusted for store type.

Newspaper advertisements and contacts in local health departments, tobaccocontrol organizations, and community programs were used to recruit the 63 minors aged 15-16 years (including 31 males and 32 females) who participated in the 1995 YTPS and 67 minors aged $15-16$ years (including 29 males and 38 females) who participated in the 1996 YTPS. The adult escorts included staff members from local

## Tobacco Sales to Minors - Continued

tobacco-control organizations. Teams consisting of one or two adults and two minors made one purchase attempt per store using the following protocol: an adult escort entered the store immediately before or shortly after one of the minors entered the store. The adult observed the transaction between the retailer and the minor and noted age-restriction signs posted inside the store. The minors could choose either cigarettes or smokeless tobacco. If asked by retailers, the minors were required to truthfully state their age and that they carried no age identification. Retailers were considered to be willing to sell tobacco products to minors if they recorded a sale on a cash register or placed the tobacco on the counter and asked for money. Retailers who refused to sell tobacco to the minor for any reason were considered to be not willing to illegally sell tobacco to the minor. If the retailer was willing to sell tobacco to the minor, the minor stated that he or she did not have enough money and left the store.

Overall, the percentage of retailers willing to sell tobacco to minors decreased from the assessment period in 1995 ( $37.0 \%$ ) to 1996 (29.3\%) (adjusted odds ratio [AOR], adjusted by type of store $=0.7, \mathrm{p}<0.05$ ) (Table 1). Although sales to minors decreased in most types of stores, the decrease was statistically significant only for convenience stores selling gasoline (from $48.6 \%$ to $28.9 \%$; odds ratio=0.4, $\mathrm{p}=<0.01$ ). From 1995 to 1996, there were similar percentages of retailers willing to sell tobacco to minors when the retailer asked for identification ( $2.4 \%$ in 1995 compared with $3.5 \%$ in 1996) or when the retailer asked either the minor's age or for identification ( $4.4 \%$ in 1995 compared with $3.3 \%$ in 1996).

However, the percentage of stores in which retailers asked minors for identification increased from $41.7 \%$ to $53.5 \%$ (AOR, adjusted by type of store=1.6, $p<0.05$ ), and the percentage of stores in which the retailer asked either the minor's age or for identification increased from $61.7 \%$ to $70.3 \%$ ( $\mathrm{AOR}=1.5, \mathrm{p}<0.01$ ). The percentage of stores that displayed age-of-sale warning signs increased from 32.6\% to 63.8\% (AOR=3.6, $\mathrm{p}<0.01$ ).
Reported by: Z Weinbaum, PhD, V Quinn, MEd, A Roeseler, MSPH, V Foster, MPH, N Bagnato, MPH, M Johnson, PhD, DG Bal, MD, Tobacco Control Section; D Walsh, Food and Drug Br, California Dept of Health Svcs; R Kropp, MA, J Keller, MPH, North Bay Health Resources Center, Petaluma. Office on Smoking and Health, National Center for Chronic Disease Prevention and Health Promotion, CDC.
Editorial Note: The findings in this report are consistent with previous reports indicating that illegal sales to minors may be effectively decreased by the combination of increased merchant education and enforcement of laws prohibiting sales of tobacco to minors, and that the requirement of proof of age by retailers is associated with very low sales rates (4-7). In this report, sales were less likely in both years when age was asked and/or identification was requested and when warning signs were present.

The findings in this report are subject to at least two limitations. First, because comparable data are available for only 2 years, they may not indicate a trend. Second, because the STAKE Act required statewide implementation, an evaluation design using control communities was not possible, and further assessment is needed to examine the possible influences of other factors on the rate of illegal sales to minors.

The efforts of government and the private sector in California provide one model approach for reducing tobacco sales to minors. For example, the STAKE Act contains strengthening provisions that were not specifically required by the Synar Amendment. In addition, the STAKE Act was amended in 1995 to prohibit the sale of tobacco

## Tobacco Sales to Minors - Continued

products from vending machines except those in bars not adjoining restaurants, while a different law ${ }^{\S}$ bans the sale of individual cigarettes from open packages. Despite these efforts, the findings in this report indicate that, for 1996, one third of stores did not post warning signs, minors were not asked for proof of age identification in approximately half of stores, and retailers were willing to sell tobacco to minors in almost one third of purchase attempts.

On August 28, 1996, the Food and Drug Administration (FDA) issued regulations that prohibit sales of tobacco to persons aged $<18$ years, require retailers to request photographic identification to verify the age of all persons aged <27 years who request tobacco, ban vending machines and self-service displays except in facilities where only adults are permitted, ban sales of single cigarettes and packages with $<20$ cigarettes, and eliminate free samples of cigarettes and smokeless tobacco products (8). The effective date for the provisions prohibiting tobacco sales to minors and requiring photographic identification is February 28, 1997, and the effective date for the provisions affecting sales through vending machines, self-service displays, single cigarettes sales, and distribution of free samples is August 28, 1997. The FDA rule should further enhance state and local efforts to decrease illegal sales of tobacco to minors. In addition, the Substance Abuse and Mental Health Services Administration has developed technical-assistance guidelines addressing statewide sampling methodologies, inspections (i.e., compliance checks), and interventions; these guidelines can be used by states to develop programs that comply with requirements of the Synar Amendment (9).

# Decreased Antibody Response to Influenza Vaccine Among Nursing-Home Residents Who Received Recalled Vaccine New York, 1996 

Following a voluntary recall in November 1996 of 11 lots* of Fluogen ${ }^{\circledR \dagger}$ trivalent influenza vaccine (Parke-Davis Division, Warner Lambert Company, Morris Plains, New Jersey), the New York State Department of Health and CDC evaluated antibody response to the 1996-97 influenza vaccine among residents ( $n=86$ ) of three nursing homes who received recalled vaccine and among residents ( $n=86$ ) of three other nursing homes who received vaccine produced by a different manufacturer. The Fluogen ${ }^{\circledR}$ lots were recalled because the monitored quantity of A/Nanchang/933/95(H3N2) hemagglutinin antigen in the 1996-97 influenza vaccine had declined since the vaccine initially was released; the reason for this decrease is unknown. The findings of this analysis indicate that, compared with elderly nursing-home residents who received influenza vaccine from a different manufacturer, residents who received Fluogen ${ }^{\circledR}$ from recalled lots had moderately lower antibody responses to the influenza A/Nanchang/933/95(H3N2) component of the 1996-97 influenza vaccine.

Medical records were reviewed for and blood samples were obtained from the 172 nursing-home residents who received influenza vaccine. Postvaccination serum samples were analyzed for antibody against all three components of the 1996-97 vaccine using the hemagglutination-inhibition test (1).

For the group of residents that received recalled vaccine, both geometric mean antibody titers and the percentage of residents with titers $\geq 1: 40$ against the A/Nanchang/933/95(H3N2) vaccine component were significantly lower than for the group of residents that received vaccine from a different manufacturer (Table 1). For both groups of residents, antibody titers were similar for the B/Harbin/07/94 and A/Texas/36/91(H1N1) vaccine components. The analysis also assessed demographic characteristics, chronic medical conditions, previous vaccination status, and activity levels; however, none of these factors accounted for the group-specific differences in antibody titers.
Reported by: H Leib, R Gallo, D Ackman, MD, L Pate, P Smith, MD, State Epidemiologist, New York State Dept of Health; R Hodder, MD, Francis Schevier Home and Hospital, Bronx; I Gomolin, MD, Gurwin Jewish Geriatric Center, Commack; FB Olsen, DDS, The Parker Jewish Geriatric Center, New Hyde Park; H Morley, Petite Fleur Nursing Home, Sayville, New York. Office of the Director, and Influenza Br and WHO Collaborating Center for Surveillance, Epidemiology, and Control of Influenza, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases; Div of Applied Public Health Training (proposed), Epidemiology Program Office, CDC.
Editorial Note: Based on the finding in New York that antibody response among nursing-home residents who received recalled Fluogen ${ }^{\circledR}$ was moderately lower than that among residents who received influenza vaccine from a different manufacturer, health-care providers might consider revaccinating persons who received recalled Fluogen ${ }^{\circledR}$. Several factors have been considered for determining whether persons who received recalled Fluogen ${ }^{\circledR}$ should receive an additional dose of the 1996-97 influenza vaccine. First, although higher postvaccination antibody levels generally are

[^4]Influenza Vaccine - Continued
TABLE 1. Geometric mean antibody titer and percentage of antibody $\geq 1: 40$ in nursing-home residents who received either recalled Fluogen ${ }^{\circledR}$ * or influenza vaccine from a different manufacturer, by vaccine component - New York, 1996

|  | Received <br> recalled <br> Fluogen <br> ® | Received <br> (n=86) | vaccine from <br> a different <br> (nanufacturer <br> (n=86) |

* Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services or the Public Health Service.
${ }^{\dagger} \mathrm{P}$ values for geometric mean titers were calculated using the Wilcoxon-rank sum two-sample test; for the percentage of residents with titers $\geq 1: 40$, the Mantel-Haenszel chi-square test was used.
associated with greater protection from influenza-like illness and its complications (2-4), there is no absolute antibody titer that ensures protection. Second, because revaccination does not ensure development of higher antibody titers, it is difficult to estimate the potential clinical and public health benefits associated with revaccination. Finally, a recent study of young adults indicated that antibody titers did not differ among groups randomized to receive either recalled or nonrecalled Fluogen ${ }^{\circledR}$ manufactured for the 1996-97 influenza season (P.A. Gross, S. Sperber, Hackensack University Medical Center, personal communication, 1996). Although the total number of persons who received vaccine from recalled lots of Fluogen ${ }^{\circledR}$ represent only $5 \%-7 \%$ of all persons nationwide who received a 1996-97 influenza vaccination, most doses of vaccine have been administered before the influenza season (October-mid-November), and all remaining supplies of 1996-97 vaccine are limited.

Based on these factors, CDC and the Food and Drug Administration recommend that physicians consider vaccinating the following persons with the remaining supplies of influenza vaccine, in order of priority: 1) all high-risk persons (5) who have not received any doses of the 1996-97 influenza vaccine, especially those with chronic medical conditions; and 2) high-risk persons, especially those with chronic, debilitating medical conditions, who received Fluogen ${ }^{\circledR}$ from recalled lots. Revaccinaton is not recommended for other persons, including healthy persons who received Fluogen ${ }^{\circledR}$ from a recalled lot.

An alternative strategy for controlling influenza type A among high-risk patients is the use of the antiviral agents amantadine or rimantadine, especially for chronically ill, institutionalized, or severely debilitated persons who have been or may be exposed to influenza type A during an outbreak. Amantadine and rimantadine are equally effective for prevention and treatment of influenza type A infection. Additional information

## Update: Influenza Activity — United States, 1996-97 Season

In collaboration with the World Health Organization (WHO), its collaborating laboratories, and state and local health departments, CDC conducts surveillance to monitor influenza activity and to detect antigenic changes in the circulating strains of influenza viruses. This report summarizes influenza activity in the United States from September 29 through December 7, 1996, and indicates that influenza activity has increased since mid-November.

From September 29 through December 7, a total of 602 (7\%) of 8927 respiratory specimens tested by WHO collaborating laboratories in the United States were positive for influenza virus. Of the 602 positive cultures, 458 ( $76 \%$ ) were reported during November 17-December 7. Of the 602 influenza isolates, 595 ( $99 \%$ ) were influenza type A, and seven ( $1 \%$ ) were type B. Of the 158 influenza type A isolates subtyped, all were $A(H 3 N 2)$. CDC further characterized 13 influenza $A(H 3 N 2)$ isolates, and all were antigenically similar to the H3N2 component of the 1996-97 influenza vaccine.

Regional influenza activity* was first reported by state or territorial epidemiologists during the week ending October 19 in Maryland and continued to be reported from one to two states each week through the week ending November 16; regional activity increased to seven, 10, and 14 states for the weeks ending November 23, November 30, and December 7, respectively. Widespread activity was first reported in Colorado and Pennsylvania during the week ending November 23, and in Connecticut during the week ending December 7. For the first time this season, the percentage of patients with influenza-like illness who visited sentinel physicians ( $5 \%$ for the week ending December 7) exceeded baseline levels (0-3\%).

During September 29-December 7, the percentage of deaths attributed to pneumonia and influenza (P\&I) as reported by the vital statistics offices of 121 cities has not

[^5]
## Influenza Activity - Continued

exceeded the epidemic threshold ${ }^{\dagger}$. Peaks in physician-reported influenza morbidity typically precede peaks in P\&I mortality by 2-5 weeks (1). As of December 7, a total of 23 outbreaks of influenza were reported to CDC; five (one in Indiana and two each in New York and Wisconsin) are described here.

## Indiana

During November 24-December 1, a total of 431 ( $65 \%$ ) of 660 persons aged 15-24 years attending a vocational training camp in Indiana had onset of acute febrile respiratory manifestations (fever $\geq 100 \mathrm{~F}[\geq 38 \mathrm{C}]$ and cough); 20 ( $10 \%$ ) of 200 staff had onset of similar illness. On November 27, three of four nasopharyngeal swab specimens obtained from ill persons were positive for influenza type A by rapid antigen-detection test. At the state public health laboratory, three of these specimens were further subtyped as influenza A(H3N2). Before the outbreak, 56 ( $9 \%$ ) camp attendees and approximately $90 \%$ of the staff had been vaccinated with the 1996-97 influenza vaccine. During the Thanksgiving break, all persons who were asymptomatic left the camp, and symptomatic persons remained at the camp. After all attendees returned to the camp on December 1, only three additional cases were identified.

## New York

During October 1-19, a total of $38(50 \%)$ of 76 residents of two of the 17 units in a 571-bed long-term-care facility in Rochester, New York, had onset of acute febrile respiratory manifestations. Of the 442 employees of the facility who responded to a questionnaire, 46 (10\%) had onset of similar illness. Of the nasopharyngeal swab specimens obtained from 15 ill residents, six ( $40 \%$ ) were positive for influenza type A at the state public health laboratory; four of these isolates were sent to CDC and further characterized as influenza A/Wuhan/359/95-like(H3N2). None of the residents or staff had received influenza vaccine before the outbreak. A total of 529 ( $93 \%$ ) residents and 581 ( $75 \%$ ) of 780 employees were vaccinated during the outbreak. Residents of the two affected units were isolated from residents of other units during October 4-18 and October 10-25, respectively. One resident was hospitalized with pneumonia.

## New York City

During November 6-16, a total of 25 (5\%) of 499 residents of a nursing home had onset of acute respiratory manifestations. All ill residents were living on seven floors of the 13 -floor facility. Fifteen ( $2 \%$ ) of 650 employees also had onset of similar illness. Of nasopharyngeal swab specimens obtained from eight ill residents, five were positive for influenza type A by a rapid antigen detection test. One of these specimens was cultured and confirmed as influenza type A. During October 1996, a total of 427 (91\%) of 470 residents for whom information was available had received influenza vaccine. During November 7-13, residents of the two floors affected first were isolated from residents of other floors, and the staff assigned to these floors did not circulate to other floors. In addition, on November 8, amantadine was administered to all 80 residents on those two floors. On November 12, amantadine was administered to all other asymptomatic residents. Nine patients were hospitalized; two developed pneumonia, and seven had exacerbation of underlying medical conditions.

[^6]
## Influenza Activity - Continued

## Wisconsin

On September 19, an outbreak of acute febrile respiratory illness began among students at a university in Milwaukee. Of the nasopharyngeal swab specimens obtained from 295 ill students, 47 were positive for influenza type A. Amantadine was administered to severely ill students. As of December 6, the outbreak was ongoing.

On November 25, an outbreak of acute febrile respiratory illness began among students at another university in Milwaukee. Seven (47\%) of the 15 nasopharyngeal specimens cultured were positive for influenza type A. As of December 6, the outbreak was still in progress.

Ten isolates from the outbreaks in Milwaukee were identified as influenza A(H3N2) virus; one of these was antigenically characterized by CDC as influenza A/Wuhan/359/ 95-like(H3N2).
Reported by: G Steele, PhD, Epidemiology Resource Center and State Epidemiologist, D Bixler, MD, M Yonker, MA, Virology Laboratory, Indiana State Dept of Health; M Schultz, G Atterbury, Job Corps; S Allen, MD, Indiana Univ Medical Center, Indianapolis. J Davis, MD, State Epidemiologist for Communicable Diseases, T Haupt, Div of Health, Wisconsin Dept of Health and Social Svcs; G Sedmak, PhD, City of Milwaukee Health Dept. L Cheney, Monroe Community Hospital, Rochester; L Villarente, DeWitt Nursing Home, New York City; D Ackman, MD, Bur of Communicable Disease Control, P Bernstein, MD, R Kirshenbaum, DO, S Kondracki, G Balzano, Regional Epidemiologist, S Switzer, G Brady, P Smith, MD, State Epidemiologist, New York State Dept of Health. Participating state and territorial epidemiologists and state public health laboratory directors. World Health Organization collaborating laboratories. Influenza Br and World Health Organization Collaborating Center for Surveillance, Epidemiology, and Control of Influenza, Div of Viral and Rickettsial Diseases, National Center for Infectious Diseases, CDC.
Editorial Note: During the 1996-97 influenza season, $99 \%$ of influenza viruses identified have been type A, and all subtyped isolates have been type $A(H 3 N 2)$. Because influenza A(H3N2) has been associated with increased morbidity and mortality among the elderly (2-4), nursing homes should routinely offer all residents influenza vaccine and should develop contingency plans for rapid administration of amantadine or rimantadine during suspected or confirmed influenza type A outbreaks. The recommended period for influenza vaccination is from the beginning of October through mid-November (5). However, influenza vaccine should continue to be offered to unvaccinated persons at high risk for complications even after influenza activity is documented in a community. During influenza type A outbreaks, amantadine or rimantadine can be administered for the 2-week period following vaccination to provide protection until vaccine-induced antibody has developed (5). Amantadine and rimantadine also are effective for treatment of influenza type A if initiated within 48 hours of illness onset.

Throughout the influenza season, surveillance data collected by CDC is updated weekly and is available through the CDC voice information system, telephone (404) $332-4551$, or the fax information system, telephone (404) 332-4565, by requesting document number 361100. Information about local influenza activity is available from many county and state health departments.

*Mortality data in this table are voluntarily reported from 121 cities in the United States, most of which have populations of 100,000 or more. A death is reported by the place of its occurrence and by the week that the death certificate was filed. Fetal deaths are not included.
${ }^{\dagger}$ Pneumonia and influenza.
${ }^{\S}$ Because of changes in reporting methods in these 3 Pennsylvania cities, these numbers are partial counts for the current week. Complete counts will be available in 4 to 6 weeks.
TTotal includes unknown ages.

## CDC Professional and Technical Staff Who Contributed to Editing, Producing, and Distributing Volume 45 of the MMWR Series

Epidemiology Program Office
Deborah A. Adams
Robert S. Black, M.P.H.
Phillip C. Bourque
Glen S. Bruce
Timothy M. Copeland
Julie T. Creasy
Evelyn B. Duval
Sandra L. Ford
Karen L. Foster, M.A.

Marjorie A. Speers, Ph.D.

The Morbidity and Mortality Weekly Report (MMWR) Series is prepared by the Centers for Disease Control and Prevention (CDC) and is available free of charge in electronic format and on a paid subscription basis for paper copy. To receive an electronic copy on Friday of each week, send an e-mail message to lists@list.cdc.gov. The body content should read subscribe mmwr-toc. Electronic copy also is available from CDC's World-Wide Web server at http://www.cdc.gov/ or from CDC's file transfer protocol server at ftp.cdc.gov. To subscribe for paper copy, contact Superintendent of Documents, U.S. Government Printing Office, Washington, DC 20402; telephone (202) 512-1800.

Data in the weekly MMWR are provisional, based on weekly reports to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the following Friday. Address inquiries about the MMWR Series, including material to be considered for publication, to: Editor, MMWR Series, Mailstop C-08, CDC, 1600 Clifton Rd., N.E., Atlanta, GA 30333; telephone (404) 332-4555.

All material in the MMWR Series is in the public domain and may be used and reprinted without permission; citation as to source, however, is appreciated.

[^0]:    * Per 100,000 population.
    ${ }^{\dagger}$ International Classification of Diseases, Ninth Revision, codes E901.0, E901.8, and E901.9

[^1]:    *Public Law 102-321, §1926 of the Public Health Service Act (42 USC §300x-26).
    ${ }^{\dagger}$ Stop Tobacco Access to Kids Enforcement (STAKE) Act: SB1927, September 28, 1994. California Business and Professional Code, Sections 22950-9.

[^2]:    *Persons aged <18 years.
    ${ }^{\dagger}$ Tests for the difference within the same year in the number of retailers willing to sell tobacco to minors between store types, whether or not retailer asked for age and/or identification, and presence or absence of warning signs.
    ${ }^{\S}$ Odds ratio (OR) for change in number of retailers willing to sell tobacco to minors from 1995 to 1996. OR for asking age and/or asking for identification, presence of warning signs, and total number of retailers willing to sell tobacco to minors were adjusted for store type.
    "Tests for the difference from 1995 to 1996 in the number of retailers willing to sell tobacco to minors.
    ** Not significant
    ${ }^{\dagger \dagger}$ Includes other store types listed by the California State Board of Equalization as selling tobacco products (e.g., gift stores and cigar stores).

[^3]:    ${ }^{\S}$ California Penal Code, Section 308.2.

[^4]:    *Lot numbers are 00176P, 00276P, 00576P, 00586P, 00676P, 00686P, 00786P, 00886P, 00966P, 00986P, and 01066P.
    $\dagger$ Use of trade names and commercial sources is for identification only and does not imply endorsement by the U.S. Department of Health and Human Services or the Public Health Service.

[^5]:    *Levels of activity are 1) no activity; 2) sporadic-sporadically occurring influenza-like illness (ILI) or culture-confirmed influenza with no outbreaks detected; 3) regional-outbreaks of ILI or culture-confirmed influenza in counties with a combined population of $<50 \%$ of the state's total population; and 4) widespread-outbreaks of ILI or culture-confirmed influenza in counties with a combined population of $\geq 50 \%$ of the state's total population.

[^6]:    ${ }^{\dagger}$ The epidemic threshold is 1.645 standard deviations above the seasonal baseline. The expected seasonal baseline is projected using a robust regression procedure in which a periodic regression model is applied to observed percentages of deaths from P\&I since 1983.
