Abstract.- Observers counted 371 swans (white birds and cygnets) in the U.S. Breeding Segment of the Rocky Mountain Population of trumpeter swans during fall of 2002, a decrease from 475 counted from comparable areas last year and the lowest count since 1993. The number of white birds (311) declined $23 \%$ from that of last year, while the number of cygnets (60) decreased by $15 \%$. Declines occurred in all 3 states in which the Tri-state Area Flocks nest, and was greatest in Montana ( $-37 \%$ ). Decreases in Idaho and Wyoming were $20 \%$ and $8 \%$, respectively. The number of birds in restoration flocks also decreased $17 \%$ compared to the count from last year. The count for the Tri-state Area Flocks this year was a marked departure from their recent upward trend in numbers. The tri-state area continues to experience drought conditions, with Palmer Drought Index values the lowest recorded since surveys were initiated in the 1930s.

The Rocky Mountain Population (RMP) of trumpeter swans (Cygnus buccinator) consists of birds that nest primarily from western Canada southward to Nevada and Wyoming (Fig. 1). The population is comprised of several flocks that nest in different portions of the overall range. The RMP/Canadian Flocks consist of birds that summer primarily in southeastern Yukon Territory, southwestern Northwest Territories, northeastern British Columbia, Alberta, and western Saskatchewan. The Tri-state Area Flocks summer in areas at the juncture of the boundaries of Montana, Wyoming, and Idaho (hereafter termed the tri-state area) and nearby areas (Fig. 2). The RMP/Canadian and Tri-state Area flocks winter sympatrically primarily in the tri-state area. In addition, efforts have been made to establish several restoration flocks, such as those at Ruby Lake National Wildlife Refuge (NWR) in Nevada (i.e., Nevada flock) and those at Malheur NWR and Summer Lake Wildlife Management Area (WMA) and vicinity (i.e., Oregon flock), by translocating adult swans and cygnets from other portions of the RMP. These birds tend to winter in areas near those where they nest. This report contains information only from the Tri-state Area and restoration flocks, collectively referred to as the RMP/U.S. Breeding Segment. These terms for the various groups of swans are consistent with the RMP Trumpeter Swan Implementation Plan (Pacific Flyway Study Committee 2002).

The Fall Trumpeter Swan Survey is conducted annually in September. The survey is conducted cooperatively by several administrative entities and is intended to provide an accurate count of the number of RMP trumpeter swans that summer in the U.S. The history of the survey dates back to the 1930s, although methods and survey coverage have changed over time as the number of swans increased and new technologies became available. Survey methodology and coverage have remained fairly consistent since 1966 (D. Olson, pers. comm.). To be consistent with previous reports, only the data from 1967 to present were analyzed for this report. The data are used by managers to assess the annual status of the Tri-state Area Flocks and restoration flocks.

## METHODS

The survey is conducted within a relatively short time frame to reduce the possibility of counting swans more than once due to movements of birds among areas. Aerial cruise surveys are used to

Fig. 1. Approximate ranges of trumpeter swans during summer (from Caithamer 2001).

Fig. 2. Map showing the 'core' tri-state area of southeast Idaho, southwest Montana, and northwest Wyoming (provided by the Greater Yellowstone Coalition, Bozeman, Montana).
count numbers of swans in the tri-state area, in Nevada, and in the Summer Lake WMA and vicinity; ground surveys are used to count the number of swans at Malheur NWR and in isolated pockets of habitat not covered by aerial surveys. During aerial surveys, data are collected by observers seated in a single-engine, fixed-winged aircraft. Flying altitude varies with changes in terrain and surface winds, but generally averages $30-60 \mathrm{~m}$ above ground level, and flight speed is between $135-155 \mathrm{kph}$. One to two observers and the pilot count white (i.e., adults and subadults) and gray (i.e., cygnets) swans in known or suspected summer habitats. Counts are not adjusted for birds present but not seen by aerial crews, and have an unknown and unmeasured sampling variance associated with them.

During fall 2002, most of the area was surveyed during 15-19 September. Ruby Lake NWR was surveyed on 25 September. Approximately 25 h of flight time and 5 h of ground survey time were required to complete the survey. Weather conditions during this time generally were warm and sunny. However, the weather in Idaho was overcast with some showers. Many areas near the Summer Lake WMA where most swans of the Oregon flock are counted were not surveyed this fall. These were the only areas traditionally surveyed that were not completed. Oregon will attempt to conduct these surveys in the future, but resource constraints may preclude them from doing so in some years (B. Bales and M. St. Louis, Oregon Dept. of Fish and Wildlife, pers. comm.).

## RESULTS AND DISCUSSION

Habitats continued to be quite dry during fall, and the tri-state area remained in a drought. By midJune, much of the summering range of RMP swans in the U.S. was in severe to extreme drought (Fig. 3). The drought intensified further as summer progressed. Recently, Palmer Drought Indices for southwest Montana have reached their lowest levels in almost 70 years (Fig. 4). Survey biologists reported that many wetland areas were dry in September (Appendix A).

## Historical Trends

During 1988-92, several significant management actions affecting the RMP/U.S. Breeding Segment occurred concurrently, including (1) the hazing of swans from wintering areas to alleviate high concentrations of birds, (2) experimental translocations of many swans from summer and winter areas to alternate sites to promote use of new wintering areas and establish alternative migratory pathways (Shea and Drewien 1999), and (3) the termination of winter feeding of swans at Red Rock Lakes NWR (U.S. Fish and Wildlife Service 1992). Collectively, these actions likely influenced the demographics of these birds, and the number of swans declined markedly ( $-46 \%$ ) between the falls of 1988 and 1993. Because the management actions mentioned above likely impacted swans in the RMP/U.S. Breeding Segment and the Tri-state Area Flocks, we partitioned the data from 1967-2001 into two time periods to assess trends in swan abundance prior to 1989 and after 1992. The first period encompassed the fall counts from 1967-88, years during which swans were provided winter food at Red Rock Lakes NWR, and translocations of cygnets and adults during fall occurred (Gale et al. 1988) but at a relatively low level (averages of about 2 cygnets and 3 adults per year) compared to 1988-92 when about 11 juveniles and 29 adults per year were translocated during summer (data

Fig. 3. Palmer Drought Index map for June 22, 2002 (Joint Agricultural Weather Facility 2002).

Fig. 4. Monthly Palmer Drought Indices for climate division 2 in southwest Montana.
in Shea and Drewien 1999). The second time period analyzed included counts from 1993-2001, immediately following the termination of winter feeding and the summer-translocation experiment. Counts for the Oregon flock also were divided into 2 time periods for analysis, but the periods were different from those used for analysis of the RMP/U.S. Breeding Segment and the Tri-state Area Flocks. Between the winters of 1991-1995, almost 600 birds wintering in Harriman State Park, Idaho and over 50 birds summering at Red Rock Lakes NWR were translocated to the Summer Lake WMA (Shea and Drewien 1999). Because of this large influx of birds, we analyzed the counts for the period prior to the translocations (i.e., 1967-91) separate from counts that occurred once the translocations were initiated (i.e., 1992-2001). Counts for the Nevada flock probably were not influenced to a large extent by any of the management actions mentioned above for the Tri-state Area and Oregon flocks (i.e., the Nevada flock is spatially disjunct from the other flocks, and no swans were moved to Nevada during 1988-96 [Shea and Drewien 1999]). Therefore, we did not partition the data for the Nevada flock, and used the entire time series of counts in analyses.

We used least-squares regression on log-transformed counts to assess changes in growth rates within the time periods analyzed for each of the swan flocks. Counts from the current fall survey (2002) were compared to results from the earlier time frames, a practice used in U.S. Fish and Wildlife Service survey reports for other waterfowl (e.g., Wilkins and Otto 2002, U.S. Fish and Wildlife Service 2002).

The counts for total swans of the RMP/U.S. Breeding Segment suggested no trend $(P=0.27)$ during 1967-88 (Table 1, Fig. 5). The number of white birds appeared to decline slightly ( $-0.8 \%$ per year), but the value for the slope parameter $(\beta)$ was only marginally significant $(P[\beta<0]=0.16)$. The counts for cygnets suggested no trend $(P=0.50)$. During 1993-2001, counts of total swans $(+2.4 \%$ per year) and counts of white birds ( $+2.9 \%$ per year) increased $(P[\beta>0] \leq 0.10)$, but no trend in the number of cygnets was evident $(P=0.76)$. Patterns for regression statistics for the Tri-state Area Flocks were similar to those for the RMP/U.S. Breeding Segment (Fig. 6), because the vast majority of birds comprising the RMP/U.S. Breeding Segment summer in the tri-state area (Table 1). However, the counts of white swans appeared to decline at a somewhat greater rate ( $-1.0 \%$ per year, $P=0.09$ ) during 1967-88, and counts of total and white swans increased ( $+3.6 \%$ and $+4.0 \%$ per year, respectively $)(P \leq 0.02)$ at greater rates during 1993-2001 compared to the entire RMP/U.S. Breeding Segment.

Birds summering in Montana (Table 2) had patterns of change relatively similar to that of the Tristate Area Flocks as a whole, because historically the swans in Montana comprised the majority of birds in the Tri-state Area Flocks. Total swans in Montana appeared to decline slightly ( $-1.2 \%$ per year) during 1967-88 (Fig. 7), although the value for the slope parameter was only marginally significant $(P=0.16)$. The decline existed only for white birds; counts for cygnets suggested no trend $(P=0.95)$. However, swans in Montana increased from 1993-2001 at a greater rate ( $\beta=$ $+6.9 \%$ per year, $P<0.01$ ) than that for the Tri-state Area Flocks as a whole, resulting from increases in the number of white birds. In Idaho, no trends in total or white swan counts were evident for the 1967-88 period, but the counts for cygnets increased ( $P=0.03$ ) (Fig. 8). During 1993-2001, a $2.8 \%$ per year increase in the number of total swans was marginally significant $(P=0.16)$. No trends in

${ }^{\mathrm{b}}$ Counts for Malheur NWR only; Summer Lake WMA survey not completed.
swan counts were evident in Wyoming (Fig. 9). However, counts during the 1993-2001 period generally were as high or higher than counts during the 1967-88 period.

No trend was evident in counts of total swans or white birds for the Oregon flock during the period 1967-91 ( $P \geq 0.34$ ) (Fig. 10). However, during 1992-2001, total swans decreased $10.0 \%$ per year ( $P<0.01$ ), and the rate of decrease in the number of white birds was $12.0 \%$ per year $(P<0.01)$. The counts of cygnets suggested no trend over the entire time frame ( $P=0.22$ ). Apparently, the large number of birds moved to Summer Lake WMA either did not survive or moved elsewhere over time. Further, the number of total swans during the last few years is somewhat lower than that during the 1960s. Recent declines at Malheur NWR may partly be the result of moving birds from Malheur NWR to nearby Summer Lake WMA during the 1990s (M. Laws, Malheur NWR, pers. comm.); modeling exercises suggest source areas may be depleted as a result of removals (Page 1976, but see Turner 1981).

Counts for the Nevada flock ranged between 6 and 42 birds during 1967-2001, with no apparent long-term trends in either white birds or cygnets (Fig. 11). However, counts of white birds in recent years have been near historic highs, and the total counts generally have increased over the short-term (i.e., last 10 years).

## Results from the 2002 survey

Because areas near the Summer Lake WMA were not surveyed this year, the fall 2001 survey data were recalculated excluding the Summer Lake WMA data to permit meaningful comparisons between 2002 and 2001 counts of the RMP/U.S. Breeding Segment. During fall 2002, observers counted 371 trumpeter swans for the RMP/U.S. Breeding Segment, a decrease of $22 \%$ from the count (475) for comparable areas last year and the lowest count since 1993 (Fig. 5). Both the number of white birds ( $-23 \%$ ) and cygnets $(-15 \%)$ declined from their respective counts last year. These drops are in contrast to the upward trend in swan abundance observed during 1993-2001.

Decreases were noted throughout the surveyed area. The largest decline in total swans from 2001 counts occurred in Montana ( $-37 \%$ ), followed by Idaho ( $-20 \%$ ), restoration flocks ( $-17 \%$ ), and Wyoming ( $-8 \%$ ). The number of white birds declined in all areas surveyed (Table 2), but was especially pronounced in Montana ( $-46 \%$ ). The number of swans at Malheur NWR in 2002 was only slightly above record lows. In Nevada, the number of white birds declined from the secondhighest count last year, but remains high relative to the long-term (i.e., 1967-2001) average. For the first time since 1996, movement by white birds into Yellowstone National Park appears to have occurred ( 5 total; 2 into northern and 3 into southern areas [T. McEneaney, pers. comm.]); however, the significance of these observations is undetermined.

Fig. 7. Numbers of swans counted in Montana during the Fall Trumpeter Swan Survey, 1967-2002 (thin and thick lines depict trends for total swans and white birds, respectively).

Fig. 8. Numbers of swans counted in Idaho during the Fall Trumpeter Swan Survey, 1967-2002 (thin and thick lines depict trends for total swans and cygnets, respectively).

Fig. 9. Numbers of swans counted in Wyoming during the Fall Trumpeter Swan Survey, 1967-2002.

Fig. 10. Numbers of swans counted in the Oregon flock during the Fall Trumpeter Swan Survey, 1967-2002 (thin and thick lines depict trends for total swans and white birds, respectively). The count for 2002 is from an incomplete survey, and is not comparable to prior years.

Fig. 11. Numbers of swans counted in the Nevada flock during the Fall Trumpeter Swan Survey, 1967-2002.

The production of cygnets increased in Montana, but declined in other areas. An index ${ }^{1}$ to production rate (i.e., cygnets/white birds) in Montana (0.237) was near the long-term (i.e., 19672001) average ( 0.267 ), but rates in Wyoming ( 0.226 ) and at Malheur NWR ( 0.500 ) were somewhat higher than their respective averages ( 0.193 and 0.390 ). The rate in Idaho ( 0.136 ) was substantially below average ( 0.208 ). For the second consecutive year, the Nevada flock fledged no cygnets.

Changes in point counts of animals can be influenced by several factors (i.e., mortality, animal movements, survey problems). The lower count of swans in the Tri-state Area Flocks observed in 2002 could be the result of one or more of these phenomena. Given the information available, we cannot ascertain which cause or causes for the decline are most likely. To date, we have no evidence to suggest that a large amount of mortality occurred. Weather in the tri-state area during winter 2001-02 was relatively mild, and biologists believe mild weather may enhance winter survival of swans in this region. Observers traversing the tri-state area to detect neck-collared swans documented the mortality of a similar number of swans to that of the previous winter (i.e., 32 during winter 2000-01, 34 during winter 2001-02 [Whitman 2002]). We do not know what proportion of the dead birds were from nesting areas in Canada versus those nesting in the U.S., so we cannot directly attribute this level of winter mortality to numerical changes in the Tri-state Area Flocks. Winter counts of RMP swans in the tri-state area were 3,917 and 4,360 during winters 2001 and 2002, respectively (Olson 2001, 2002). Of the 7 swans with neck collars that died during winters 2000-02 (S. Bouffard, Minidoka NWR, pers. comm.), 3 of the birds had been sighted in Canada at least once, and 3 birds died the same winter in which they were banded so their breeding-ground affinity could not be surmised. The remaining swan was resighted only in Idaho during each of 6 winters. However, all of the sightings of this bird were between 8 November and 25 March, so the breeding-ground affinity of this bird also is uncertain. Finally, observations by biologists through April also did not document significant incidences of mortality in late spring (D. Munoz, Southeast Idaho Refuge Complex, pers. comm.).

Nonetheless, no systematic surveys to detect swan mortality are conducted. In many instances, dead swans are detected by casual observations of individuals. Therefore, our ability to detect changes in mortality is limited, especially if that mortality is at a relatively low level over a broad expanse of land or if it occurs in areas that are not typically visited.

The count this fall departed substantially from the upward trend in swan numbers since 1992, and monitoring data currently available do not allow us to determine a biological cause for the sudden and dramatic decline. Certainly, the count should be cause for concern. However, at this point data

[^0]do not exist that indicate the decrease is due entirely to mortality, or to confirm that the size of the Tri-state Area Flocks has been reduced by $23 \%$. Nonetheless, we also should not simply dismiss the number as an aberration. Survey results for the next few years will be critical to assess whether the decrease in birds counted this year is an anomaly or an indication of changing demographics.

## ACKNOWLEDGMENTS

We would like to especially thank the personnel who conducted the surveys, a list of whom is provided in Appendix B. The survey is a collaborative effort among Red Rock Lakes NWR, Migratory Birds and State Programs -- Mountain-Prairie Region of the U.S. Fish and Wildlife Service, Southeast Idaho Refuge Complex, National Elk Refuge, Harriman State Park, Idaho Department of Fish and Game, Grand Teton National Park, Yellowstone National Park, Wyoming Game and Fish Department, Ruby Lake NWR, Malheur NWR, and the Shoshone-Bannock Tribes. S. Comeau compiled the data. S. Bouffard (Minidoka NWR) provided resighting data for neckcollared swans. S. Comeau, J. Cornely, M. Laws, T. McEneaney, C. Mitchell, S. Patla, J. Mackay, and D. Olson reviewed a previous draft of this document. S. Bouffard and R. Shea also provided comments.

| Whiskey Creek |  |  |  |  |

${ }^{2}$ Blank denotes area not surveyed.

## Appendix B. Personnel who conducted the 2002 Fall Trumpeter Swan Survey in the U.S.

```
Montana (Red Rock Lakes NWR, Centennial Valley, Madison Valley)
    Observers: S. Comeau and G. Dehmers (Red Rock Lakes NWR)
    Pilot: B. Twist (Western Montana Aviation)
Montana (Paradise Valley)
    Observer: T. McEneaney (Yellowstone National Park)
    Pilot: R. Stradley (Yellowstone National Park)
Idaho
    Observer: C. Mitchell (Gray's Lake NWR)
    Pilot: G. Lust (Mountain Air Research)
Wyoming
    Observer: S. Patla (Wyoming Game and Fish Department)
    Pilot: G. Lust (Mountain Air Research)
Wyoming (Yellowstone National Park)
    Observer: T. McEneaney (Yellowstone National Park)
    Pilot: R. Stradley (Yellowstone National Park)
Ruby Lake NWR and vicinity
    Observers: J. Mackay and M. Collins (Ruby Lake NWR)
    Pilot: R. Cassinelli (El Aero Services)
Malheur NWR
    M. Laws, R. Roy, T. Hallock, D. Morris, A. Renc, and K. Vargas (Malheur NWR)
Summer Lake WMA
    M. St. Louis (Oregon Department of Fish and Wildlife)
```

[^0]:    ${ }^{1}$ A better method to assess annual productivity is to estimate the number of young produced per breeding pair, because a proportion of white birds each year are subabults or adults that did not nest. Traditionally, such information was provided in this report. However, those data are not collected as part of the Fall Trumpeter Swan Survey. In past reports, methods describing how the data are collected, areas covered, and effort expended have not been reported. Further, issues regarding proprietary rights to those data have been raised. For these reasons the data have not been included in this report. Recently, the Greater Yellowstone Trumpeter Swan Working Group (GYTSWG) has been tasked with developing data-collection protocols and reporting formats (Pacific Flyway Study Committee 2002:14). The issue of how those data are reported should be discussed by the GYTSWG.
